"From this discovery of our great countryman [Harvey] many improvements even in the cure of distempers might be made. He had thoughts of composing such a work himself to show the advantages of this doctrine in relation to practice but was prevented by sickness and death. The design of the Architect was very noble and I with some of his successors might finish it. At present I shall hint only at two or three particulars which will convince us of what use a perfect knowledge of the circulation may be to us, if rightly applied, in the practical part of our profession."

If more than two centuries ago the learned author of *The History of Physic from the Time of Galen to the beginning of the xvi Century* apparently thought the task difficult and accordingly acted with wise discretion, it is now obviously, from limitations of both time and capacity, impossible to attempt more than the barest outline of the accumulated knowledge of the diseases of the circulatory system since Harvey's time. An attempt to piece together the history of the various forms of cardiac disease is attended by no small difficulties: the same ideas often occur to several minds at the same time, but simultaneous and identical solutions are not published synchronously, thus making it far from easy to decide who really deserves the rather barren crown of priority. Another obvious objection to such a subject is that it entails lists of men and dates, but as many of these names are those of Fellows of this College it will surely be in obedience to Harvey's injunction to commemorate these benefactors of the College, for can any benefaction be more welcome than new and true knowledge?

The knowledge of cardio-vascular disease, which was very slight at the time of the discovery of the circulation,

has since come through several channels: (1) the accumulation of data provided by anatomical observation, normal and morbid, (2) unaided clinical observation, (3) as the result of the application of instruments of precision to the examination of patients, and (4) the information derived from physiological and pathological experiments. Though these four headings are attractive as a means of sketching the advance of knowledge, it is in practice difficult, and indeed somewhat inconvenient, to follow them out rigidly or attempt to make them absolutely watertight, there will therefore be much overlapping, as will at once be only too obvious.

ANATOMICAL OBSERVATION

Anatomy is an indispensable step to the more complex science of physiology, which explains the vital forces of the body, and thus, though it may be helped by anatomy, demands observation of, or experiment on, the living organism. Fabricius's description of the valves in the veins stimulated Harvey to find out their use by the experimental method. Gaskell's physiological demonstration of the muscular continuity between the auricle and the ventricle was made on reptiles, and was supposed to be confined to them until 1893, when the auriculo-ventricular bundle was described in mammals by Stanley Kent and by W. His, junior, in 1906. Tawara gave a full account of the junctional system, including the auriculo-ventricular node and the bundle previously described by Kent and His, the fibres of the bundle being continued into the Purkinje fibres which line the interior of the ventricles and communicate with their muscular fibres, this was followed in 1907 by Keith and Flack's discovery of the sino-auricular node, the normal pace-maker of the mammalian heart, the later anatomical observations were subsequent to, and directly stimulated by, the needs of the new cardiology, for Mackenzie's epoch-making book on the pulse was published in 1902. Thus it may be noted that, just as medicine is deeply indebted to the experimental method, so also science owes a debt to medicine, and that they two "according well may make one music as before."

The Capillaries

The tercentenary of the birth of Marcello Malpighi, the father of histology, on March 10th, 1628, and that of the *De Motu* appropriately coincide, for in 1661 he provided the final proof of Harvey's discovery by recognizing the capillaries in the frog's lung. He also saw the red blood corpuscles in the mesenteric vessels of a hedgehog, but as he regarded them as fat cells, Antony van Leeuwenhoek, who described them fully in his *True Circulation of the Blood* in 1686, has the credit of their recognition. Johannes Swammerdam, however, had actually noted the presence of red blood cells as early as 1658, but his observation was not made public until 1738, when Boerhaave brought out Swammerdam's *Biblia Naturae*.

After the discovery of the capillaries there was a long interval before this most essential part of the circulatory system received due attention. Thomas Young in 1808 had the foresight to assume as probable variation in the size of the capillaries. The view that the capillary circulation was a mere passive communication between the arterioles and the venules was definitely modified by Stricker's observation in 1865 that the capillaries became constricted from swelling of the endothelial cells. In 1873 Rouget observed on the surface of capillaries the cells which bear his name, and described their contraction. In 1879 Roy and Graham Brown showed that the calibre of the capillaries is constantly changing without corresponding alterations in the arteriolar pressure. The study of the capillary circulation then languished, but the invention of capillary microscopy by Lombard in 1912 again stimulated investigation, and it has now been proved that the walls of the capillaries have independent powers of changing their calibre.

The capillary circulation, thanks to the experimental labours of Dale, Laidlaw, Richards, Krogh, and Lewis, has been placed in a new light. It appears that the capillary area as a whole is in a constant state of flux, while the great portion is relatively empty, various parts of it open for a time, so that with a constantly changing

condition of the constituent portions the average total path remains about the same and maintains the peripheral resistance. Normally only a very small proportion of the whole available capillary area is open, for if it were universally open all the blood would stagnate there. The varying dilatation of the capillaries corresponds, as Krogh demonstrated in muscle, with the needs for it.

The question whether the circulation in the nervous system, the lungs, and the coronary vessels is under the same nervous control as the rest of the general systemic capillaries has been exhaustively investigated and is referred to briefly elsewhere, the effect of adrenaline on the vessels—contraction or its absence—has been employed as a criterion of the presence or absence of vasomotor fibres, but can hardly—for example, in the case of the coronary arteries—be regarded as devoid of exceptions due to a species difference in the nerve supply and reactions.

Morbid anatomy must also be supplemented by clinical observation or by experiment, the example set by Harvey of always submitting to the test of physiological proof the explanations suggested by anatomy, which is completely instructive only when elucidated by physiological experiment, was followed with regard to morbid anatomy and its correlation with symptoms by Morgagni, Corvisart, Laennec, Hope, and later the experimental results obtained by Claude Bernard, Cohnheim, Roy, Starling, and many others were brought to supplement the teaching of the *post-mortem* room.

It was not until the eighteenth century, with the publication of observations on morbid anatomy made by Raymond Vieussens (1715), Lancisi (1718, 1740), and Morgagni (1761), and the first treatise dealing specially with diseases of the heart by J. B. de Senac (1749), that cardiac disease was really recognized. Theophilus Bonetus, in the first volume of his *Sepulchretum* (1679), collected a number of observations on palpitation and cardiac pain during life associated with polyp in the heart, calculi in the myocardium, inflammation of the heart, acute inflammation, effusion, and adhesion of the pericardium, and aortic aneurysm, and thus prepared the way for Morgagni and others. Vieussens and Morgagni recorded a number of valvular lesions, and Lancisi in 1718 described vegetations on the valves and noted dilatation and hypertrophy, but applied the term "aneurysm" to the former, in his posthumous book (1740) syphilitic lesions of the heart were outlined. De Senac described ulceration, abscess, and inflammation of the heart, "the hairy heart" of aortic pericarditis, and, in a short chapter, malformations.

Corvisart and his pupils, Laennec and Bouillaud, carried on the anatomico-clinical investigation of cardiac affections, and among the Fellows of this College James Hope (1801-41) set a fine example in this respect.

[The Quater then considered in some detail the anatomico-clinical history of various cardio-vascular diseases.]

UNAIDED CLINICAL OBSERVATION

Under the heading of unaided clinical observation the use of the stethoscope may perhaps be included, as it is artificial to separate the employment of this instrument of precision from that of direct auscultation. In this section the history also is outlined of some cardiac disorders—dyspnoea, angina pectoris, coronary thrombosis, the Stokes-Adams syndrome—which give rise to characteristic clinical pictures. As would naturally be anticipated the history of cardiac diagnosis shows that in the main recognition and correlation of symptoms came first and the invention of physical methods of examination later. Albertini of Bologna laid stress on palpitation and dyspnoea as evidence of cardiac disease, and ascribed the latter to venous stasis in the lungs. He also made use of palpation, which was little employed before his time, or indeed for a hundred years after, until Corvisart revived it and drew attention to thrills.

Percussion was described by Leopold Auenbrugger of Vienna in a pamphlet of twenty-two pages in 1761, the year in which Morgagni's great work on morbid anatomy, *De Sedibus et Causis Morborum*, appeared, and so should have been a means of correlating physical signs with gross structural changes. But though praised as worthy of all attention by his senior contemporary Albrecht von Haller

of Berne, and translated into French by Rozier de la Chassagne, and published in Paris in 1770, the conservatism responsible for opposition to Harvey's discovery delayed the acceptance of Auenbrugger's percussion. It was thus long before its time and did not receive any recognition until, in 1808, the year before the author's death, J. N. Corvisart translated it into French for the second time.

Auscultation, though in practice and in our minds dating from Laennec and the invention of the stethoscope, was not an absolutely new idea in 1819. The story of the invention of the stethoscope by Laennec has often been told. In 1816 he noticed boys in a court of the Louvre at play with the ear applied to long pieces of wood listening to the transmitted sound of a pin scratch at the opposite end. He immediately put this hint into practice, as he says, by applying a rolled up quire of paper to the chest of a stout girl with symptoms of heart disease, and was electrified by finding that the heart sounds were more audible than to the direct ear. He keenly practised this method at the Necker Hospital, where, however, Granville, as an onlooker on September 16th, 1816, states that the original birth of mediate auscultation actually occurred on the chest of a male patient. Laennec then devised a wooden cylinder $1\frac{1}{2}$ inches in diameter, a foot long, and perforated longitudinally by a bore three lines wide, this he regarded as too simple to require a name other than "the cylinder" or "baton", but eventually, as somewhat barbarous names, such as "sonometra," "pectorilogue," "thoracoscope," "cornet de papier," and "cornet médical," appeared on the horizon, he suggested, if it must have a name, "stethoscope." With his knowledge of morbid anatomy he correlated the local lesions with the corresponding physical signs, like his teacher Corvisart, thus advancing the anatomico-clinical method and the special pathology of the organs, and in the extraordinarily short time of three years his classical work *Auscultation médiate* appeared, about August 15th, 1819. While correcting the proofs he had been busily making stethoscopes so that every buyer of his book might be properly equipped, in fact, it is probable that at the time of his death every existing stethoscope was the work of his hand (Thayer).

Though the stethoscope has some obvious advantages over the naked ear, the enormous advances that followed its introduction were not so much due to the stethoscope as a mechanical instrument as to the psychological effect that this new method exerted on Laennec, who otherwise would not have so ardently pursued auscultation as a means of diagnosis. It was much the same with regard to the pleximeter introduced by P. A. Piorry in 1828, which in itself, apart from its temporary influence in stimulating investigation, is inferior as a method of eliciting physical signs to Auenbrugger's direct percussion, which it was intended to supersede.

Laennec's original stethoscope underwent modifications by him, by Piorry, who reduced the thickness of the stem to that of the finger, by C. J. B. Williams, and others. The invention of the binaural stethoscope was the subject of some dispute as to priority, as is shown in the pages of the *London Medical Gazette* for 1840-41. Sibson used one in 1838, Burne in 1840, and Golding Bird stated that Babington at Guy's Hospital had used one for some time. In America, where it was introduced in 1850 by Cammann, its vogue became general much earlier than in this country. Auscultatory percussion, or a combination of the two methods enabling the vibrations produced by percussion to be directly transmitted to the ear by the stethoscope, was advocated by Cammann and Clark in 1840. More modern developments are the phonendoscope and the differential stethoscope.

Until auscultation had become somewhat elaborated the diagnosis of heart disease depended on general symptoms, such as dyspnoea, palpitation, a weak and irregular pulse, and there was not any discrimination in diagnosis. In the posthumous edition of Matthew Baillie's *Morbid Anatomy* (1825) it is stated that "no observations have yet been made by which practitioners can ascertain with any precision what set of valves is diseased." But Laennec's *Auscultation médiate* stirred the waters to much purpose. Bouillaud, Hope, Williams, and Elliotson bear

extremely active in tabulating the physical signs with the valvular lesions and accumulating data—the time, propagation, and characters—so as to determine the significance of murmurs. Hope's *Treatise on Diseases of the Heart and Great Vessels* (1832), though somewhat unwarred by his disputes with Bouilloud, chronicled a most notable advance, having carried on experimental research he was able to apply physiological principles to unravelling the haemodynamic problems of cardiac disease.

During the latter half of the last century an exaggerated importance was attached to cardiac, and especially systolic, murmurs as evidence of heart disease. With "the passing of morbid anatomy," or the overshadowing of gross morbid changes by the renewed attention to symptoms and physiological efficiency, there has now resulted a diminution in the importance attached to the physical signs of cardiac disease. But the traditional stress laid on the presence or absence of a murmur as the criterion in determining whether the heart was or was not seriously affected, though qualified by the warnings of W. T. Gardner (1862), Thomas Watson, Andrew Clark, G. W. Balfour, and others, did not become fully discounted until after the war, and then largely by Mackenzie's insistence.

CARDIAC DYSPOEIA

As a result of work done during and since the war, cardiac dyspnoea may be divided into (1) simple, in which there is increased irritability of the respiratory centre from oxygen want brought about by diminished blood supply to the centre, in these cases, occurring in the young, especially with mitral stenosis, and comparatively early, the cyanosis being bright, Fraser, Ross, and Dreyer found a definite alkalaemia, and Lewis and Barcroft noted the absence of acidemia, (2) cases of a more complicated nature, often arterio-sclerotic or cardio-renal, in older people, with myocardial degeneration, dyspnoea occurring later and the cyanosis being of a leaden hue (Fraser). In these cases there is acidemia (Lewis and Barcroft) and stimulation of the respiratory centre by the increased hydrogen-ion concentration, the fundamental idea that acidemia causes breathlessness being directly deducible from Haldane and Priestley's work (1905). These cases manifest true cardiac asthma with a sudden onset, which was ascribed by Lewis, Ryffel, Wolf, Cotton, and Barcroft (1913-14) to sudden waves of acidemia. The attacks are probably much allied to those long known as renal asthma, which, as pointed out by Loonns (1873) and Stephen Mackenzie (1889), are greatly benefited by hypodermic injection of morphine. These paroxysmal attacks of cardiac asthma were mentioned by Heberden, who culminated from his picture of angina pectoris the symptoms of breathlessness, but there is a close relation between the three conditions of angina pectoris, oedema of the lung, and cardiac asthma (Prott), which may be combined or confused with each other. Hope in 1839 gave an account of cardiac asthma, but rather confused the issue by bringing in ordinary cardiac dyspnoea and Cheyne-Stokes respiration. Clinically James Mackenzie drew special attention to the true cardiac asthma about which scepticism had been expressed. The value of morphine hypodermically in the paroxysmal dyspnoea of cardiac asthma has recently been emphasized (Fraser), and it may be noted that, on more general grounds, Clifford Allbutt in 1869 recommended morphine in cardiac disease by the then comparatively new method of hypodermic injection, the syringe having been invented by F. Ryd in 1845 and Alexander Wood in 1855.

ANGINA PECTORIS

Angina pectoris was first described on a good basis of cases, twenty in number, by the British Celsus, William Heberden the elder, in a paper entitled "Some account of a disorder of the breast," read before this College on July 21st, 1768. In the text he says "The seat of it, and sense of strangling and anxiety with which it is attended, may make it not improperly called angina pectoris," and his posthumous *Commentarii de Morborum Historia et Curatione*, 1802, show that altogether he had seen a hundred cases. Isolated cases had been reported before this. Seneca in his epistles to Lucilius recorded his

own sufferings, which may well have been those of angina sine dolore, and at any rate were by his medical attendants called a "Meditatio mortis", the Earl of Clarendon described the sudden death of his father, Henry Hyde, in 1632, and Morgagni the case of a woman who died in 1707 with a characteristic distribution of the pain and was found to have a dilated and calcified aorta. Hoffmann recorded another single case "de spasmo proecordiali a motu corporis" in 1734, Rougnon, professor of medicine in the University of Besançon, wrote a letter to M. Lorry dated February 23rd, 1768, earlier in the same year as Heberden's more complete account, describing a case of angina with a necropsy, and accordingly in France a claim for priority was made for him by Huchard. On November 17th, 1772, two further communications on the subject were made to the College, Heberden read a letter addressed to him by a man signing himself "Unknown," who, having seen an abstract of Heberden's original paper in *The Critical Review*, recognized the resemblance to his own experiences, gave an account of them, considered by Osler as one of the best extant, and expressed a wish that in the event of his death there should be a necropsy, this, when performed by John Hunter, did not reveal anything save slight calcification of the aorta, but Edward Jenner, who was present, wrote to Caleb Hillier Parry, "I can almost positively say the coronary arteries of the heart were not examined." The other, though less dramatic, communication made at this meeting, by John Wall of Worcester, has perhaps hardly received its due meed of attention, for in his letter to Heberden describing the post-mortem examination of a case of aortic stenosis with angina, the first inch of the aorta is stated to have been partly ossified, and the spasm of the pectoral muscle is ascribed to "an irritation on the nerves of the thorax and heart," and the following comment is added "Perhaps it may throw some light on this affair to consider that the nervi intercostales or sympathetici distribute many branches to the heart, arteria pulmonalis, and aorta." He thus, perhaps, in the first place anticipated James Mackenzie's view that the pain of angina is partly due to spasm of the intercostal muscles and Charlton Briscoe's suggestion that the spread of pain depends upon irritation of one of the expiratory muscles, and in the second place suggested Corrigan's and Clifford Allbutt's conception of the aortic origin of anginal pain. The association of coronary disease with angina was first recognized by Edward Jenner from post-mortem examination, though it is possible that John Hunter, on whose account, as his anginal symptoms dated from 1773, Jenner kept silence, knew or suspected it in 1776, when John Fothergill published a fatal case of angina in which at the necropsy Hunter found that "the two coronary arteries from origin to many of their ramifications on the heart were become one piece of bone." Jenner, who is said to have diagnosed angina in Hunter in 1777, never directly published anything on this subject, but he communicated his opinions to C. H. Parry, who in 1788 read a paper—"An inquiry into the symptoms and causes of the syncope anginosus, commonly called angina pectoris, illustrated by dissections"—to a small medical society in Gloucestershire of which Jenner was a member, and came to the conclusion that coronary disease was the cause. In this paper, not published until eleven years later, he quoted the case of ossification of the coronary arteries published by Black of Newry in 1795, and pointed out that he and Jenner had independently come to the same opinion in 1788.

The explanation of the causation of angina pectoris by coronary disease was, as pointed out by Osler, given by Allan Burns, the Glasgow anatomist and surgeon, who in 1809 ascribed the symptoms to anaemia—or, as it might now be expressed, anoxaemia—of the heart muscle resulting from coronary obstruction. This conception is now known as intermittent claudication—a term introduced by Bouley in 1831 in regard to horses and applied to man by Chrociot in 1858—and perhaps more intelligibly as intermittent limp (Erb). Benjamin Brodie in 1846 explained angina pectoris on these lines rather more fully, and Potain in 1870 expressed the same opinion. The view that disease of the base of the aorta was one of the causes of angina pectoris, perhaps dimly foreshadowed by Wall (1772) and

Baumes of Montpellier (1808), was put forward by Dominic Corrigan in 1837, and independently by Allbutt from 1894, with confirmation from our Honorary Fellow, K. F. Wenckebach, in the special lecture he gave in this library on May 5th, 1924, when he accordingly advocated division of the depressor nerve. James Mackenzie considered that angina is due to cardiac failure, a revival of the view held by Parry (1799) and supported by Stokes (1854), and Danielopolu put forward the slightly different explanation that myocardial intoxication by fatigue products is responsible for angina.

The syndrome of angina pectoris, ascribed to various factors, has been divided into (1) true organic or major, and (2) functional, pseudo, mock, false, vasomotorial, or minor. John Latham (1813) described a spurious form as angina nothi, Laennec (1818), who had two attacks, did not accept coronary disease as the cause, considered mild cases as common, and described it as neuralgia of the heart. Desportes (1813) had previously expressed a similar view. Forbes, the translator of Laennec's *Auscultation mediate*, spoke of organic and of functional angina, subdividing these two main categories. Lartigue (1846) and Walke independently introduced the term "pseudo-angina," which has not escaped criticism from Allbutt and Mackenzie. Nothnagel in 1867 brought in the term "vasomotorial angina," and toxic angina, especially that due to tobacco, was described by Huchard. Angina sine dolore, a form of true or major angina, was so named by W. T. Gairdner (1877). The distribution of pain and cutaneous tenderness was investigated by James Mackenzie (1892) and Henry Head.

Division of the cervico-thoracic sympathetic containing the sensory nerves of the heart and aorta as a means of relieving the pain of angina was suggested in 1899 by François-Franck, the physiologist, but not put into practice until 1916 by Jonnesco of Bucarest. The treatment by amyl nitrite was initiated in 1867 by Lauder Brunton, when a house-physician, on the grounds that he found the blood pressure high in an attack and, having heard from Arthur Gamgee that amyl nitrite lowered the blood pressure, logically and successfully employed this drug.

In the tercentenary year of the publication of the *De Motu Cordis* it is interesting to find that the coronary circulation, on which R. Lower, R. Vieussens (1706, 1715), and Adam Christian Thebesius (1708) worked, has been investigated after the Harveyan manner. Wearn finds that the blood in the coronary arteries may pass into the Thebesian vessels and so into the ventricles or auricles without entering the capillaries, there being either a direct communication between the coronary arteries and the Thebesian veins, or more probably between the arteries and large veins and thence into the cavities of the heart. Further, he argues, from observations on two cases of gradual complete obliteration of the orifices of both coronary arteries, that the Thebesian vessels may take on the new function of supplying the heart muscle with blood from the cavities of the heart a view to some extent previously expressed by Pratt. The coronary blood flow depends on the arterial pressure, but opinions differ as to the relative importance of the diastolic and systolic blood pressures in the aorta. In this year Aurep and King have shown by experiment that the coronary blood flow is not determined by either the diastolic or the systolic pressure in the aorta singly, but follows closely changes in the arithmetical average of the diastolic and systolic aortic pressures, which in most cases is a sufficiently accurate measure of the true mean pressure.

CORONARY THROMBOSIS

The syndrome of thrombosis of the coronary arteries, long included in angina, has quite recently been isolated, though Harvey's description of Sir Robert Dore's case, in his second Disquisition to J. Riolan in which the wall of the left ventricle was ruptured apparently as the result of "an impediment to the passage of the blood from the left ventricle into the arteries" has now been recognized as an early example (Wearn). The syndrome, first described in 1910 by Obrastzow and Strachenko and again in 1912 by J. B. Herrick, is, now that its characteristic features have been pointed out, obviously a frequent event

this year. Parkinson and Bedford published one hundred clinical cases and in addition eighty-three *post-mortem* cases. Isolated cases had been reported in 1884 by Leyden and even diagnosed by Hammer in 1878, and it is now easy to wonder why coronary occlusion, long recognized pathologically, had not been correlated earlier with a clinical picture. Cases of angina with pericarditis had been recorded (Steell), and the occurrence of the status anginosus, or pain lasting for hours or days, in contrast to the pain of angina, which is a matter of minutes, was noted by Huchard. Both these phenomena belong to the syndrome of coronary thrombosis. Rapid and sudden death may be due to ventricular fibrillation or to rupture of the infarcted area as in Harvey's case, recovery may occur, but myocardial failure, cardiac aneurysm, rupture, or recurrent thrombosis may follow.

STOKES-ADAMS SYNDROME

J. B. Morgagni in 1761 mentioned two men aged 68 and 64 years with slow pulse rates, one "twenty-two without one-sixtieth part of an hour," dating from the time they were "first attacked with epileptic paroxysms, beginning from the belly". Heberden in 1768 described a pulse seldom above thirty associated with torpidity. Andrew Duncan described the same events in 1793. Bright in 1831 recorded the clinical features of a case with a necropsy showing a much enlarged heart. The condition was called "maladie de Stokes-Adams" by Huchard after the two Irish physicians, Robert Adams and William Stokes, who gave accounts of it in 1827 and 1846 respectively and laid much stress on fatty degeneration of the myocardium, indeed, they transferred to that condition many of the symptoms of complete heart-block. This, of course, was long before Gaskell's physiological explanation (1883) of heart-block, which is usually, but not invariably, primarily responsible for the syndrome. Galabin in 1875 first published tracings of the independent contractions of the auricles and ventricles, and ten years later Chauveau's tracings also showed this in a man with an auricular rate of sixty to sixty-five and a ventricular rate of twenty-one to twenty-four. Osler pointed out the various forms of the Stokes-Adams syndrome, especially the rare cases with gross extrinsic lesions exerting pressure on the medulla or the vagus, such as those of Holberton, Leprie, and Boffard, and to his writings the general recognition of the syndrome is due in no small degree. Recently it has been shown that the ventricle may pass into fibrillation, and that the direct injection of adrenaline into the heart will start the circulation again even if it has stopped for four or five minutes. Subcutaneous injection of adrenaline has been found to arrest the syncopal attacks (Phear and Parkinson), but not to prevent them. For this purpose Colin and Levine had recourse to barium chloride by the mouth, which, by increasing the irritability of the ventricle, was successful in preventing the attacks. An interesting account of his own experiences during the last seven years of his life was given by W. T. Gairdner.

EXAMINATION OF PATIENTS WITH THE AID OF INSTRUMENTS OF PRECISION

Sphygmomanometry

The history of blood pressure really begins with Stephen Hales, minister of Teddington, who with a sound training in Newtonian physics, applied this knowledge to biology and physiology. Before 1723 he tied tubes into the arteries and veins of animals and estimated the pressure in the capillaries, thus being far in advance of his time. In a mare he found that the blood pressure was equal to a column of blood of eight to nine feet. Nearly a century passed before the subject was further investigated, and then Poiseuille (1828) employed a U-shaped mercurial manometer (haemodynamometer). The clinical estimation of blood pressure by instrumental means was first attempted by Vierordt in 1855 by measuring the weight necessary to stop the arterial pulsation, but von Basch, in 1880, invented a sphygmomanometer on this principle, which was applied locally over an artery and was widely used. This underwent modifications among others by Potain, Marey, Mosse, and Hürthle. Attention should be drawn to F. A. Mohomed's laborious observations on blood pressure made between 1874

and 1881, not with a sphygmomanometer, but with his own form of Marey's sphygmograph, which led him to anticipate much that is now known and far more easily verified—for example, he described a pre-albuminuric rise of blood pressure in Bright's disease, which, with von Basch's conception of "latent arterio-sclerosis" and Huchard's pre-sclerosis, led up to the recognition of primary or essential high blood pressure or hyperpiesia. The present sphygmomanometric methods became generally available as a result of Riva-Rocci's modification of von Basch's instrument. The publication of Korotkoff's auditory or auscultatory method in 1905 has made estimation of the diastolic pressure both easy and accurate for all conditions except some cases of aortic regurgitation.

The general use of the sphygmomanometer in this country was largely due to Clifford Allbutt, Bruntow, and G. Oliver. The greater stability of the diastolic than of the systolic pressure, and therefore its greater diagnostic value, the importance of the pulse or differential pressure, and a correct estimation of the significance of abnormal pressures have gradually become established. Allbutt described the occurrence of high blood pressure without renal disease, and introduced for this the word "hyperpiesia." He also insisted that long-continued high blood pressure may cause, but is not due to, arterio-sclerosis.

The sphygmograph, first invented by K. Vierordt in 1855, and improved by Marey (1860), who did so much to popularize the method of graphic registration, Mahomed (1872), Burdon-Sanderson (1867), R. E. Dudgeon (1882), Pond, von Jaquet, and others, was much used, though the information it provided was somewhat limited, it was the first step in the application to cardiology of the graphic method of record, which has since thrown so much light on haemo-dynamics. By means of his clinical polygraph (1902) James Mackenzie, then of Burnley, correlated the arterial and venous pulses with those of the heart, and thus brought order out of the chaos of cardiac irregularities, distinguishing the unimportant, such as the extrasystoles of sinus arrhythmia, from those, such as pulsus alternans, pathognomonic of grave organic disease of the heart muscle.

The Electro-cardiograph.—The potential bearings of investigating the electric currents produced by the cardiac contractions, recognized in 1843 by Matteucci of Pisa and in 1856 by Kölliker and Müller, were examined with the capillary electrometer by Sanderson and Page (1878), Gaskell (1891), Starling and Baylis (1890), and A. D. Waller. In 1903 Willem Einthoven of Leyden first described the string galvanometer, which was a great advance on the capillary and other galvanometers, and utilizing Waller's observation that curves of the cardiac contractions can be obtained from the limbs of animals without opening the chest, he, as Sir Thomas Lewis says, laid the foundation of human and experimental electro-cardiography, and by papers published in 1907 and 1908 led to modern electro-cardiography and the final analysis of the arrhythmias. The fundamental knowledge thus acquired by methods demanding delicate instruments it has fortunately been possible to correlate in many instances with simple indications which can be employed at the bedside. Wenckebach, Thomas Lewis, and their followers have thus exactly localized the site of disorders and morbid changes in different parts of the heart muscle, and particularly in the junctional system, such as lesions of the right or left branch of the auriculo-ventricular bundle, and the Purkinje arborizations, thus providing evidence of myocardial degeneration and impending cardiac failure earlier than can be detected by other means of examination.

Auricular flutter was described as long ago as 1837 by MacWilliam as the result of weak faradization of the mammalian auricles. Clinically, however, it was not recognized until much later by W. T. Ritchie and by Hertz and Goodhart. A healthy auricle responds to a single stimulus by a single contraction, but if the refractory period of a ring of muscle, as in the auricles, is shortened, the wave of contraction travels round continuously and is spoken of as a circus movement. This physiological observation of G. R. Mines was further elucidated as the condition in auricular flutter by Thomas Lewis and his co-workers. The

auricles contract extremely rapidly—200 to 300 or more times a minute, the ventricular rate being usually half that. The treatment consists in the production of a certain degree of heart-block by digitalis, or more radically by directly acting on the muscular tissue of the auricle by quinidine sulphate.

The development of knowledge about auricular fibrillation illustrates the close interdependence of clinical medicine and experimental work. Auricular fibrillation, long familiar to physiologists, was first recognized in man by Cushing and Edmunds in a case under their care in 1901 and published in 1906, the fibrillation being ascribed to vagal inhibition, but their diagnosis of fibrillation was received with doubt. In 1902 Mackenzie had recognized the complete irregularity of the pulse now known to be characteristic of auricular fibrillation, and on the ground of the absence of the auricular wave in the jugular tracings argued that the auricles had ceased to contract and were paralysed. In 1907 he abandoned the idea of paralysis, as in some cases, at any rate, the muscular fibres of the auricles were found by Keith to be hypertrophied, and argued that the auricular and ventricular contractions occurred simultaneously as the result of irritability of the auriculo-ventricular node, and called this "nodal rhythm." In 1910 Rothberger and Winterberg, and Lewis, by means of the electro-cardiograph, proved that the auricular condition was one of auricular fibrillation. The condition of nodal rhythm or simultaneous contractions of the auricles and ventricles due to the stimulus starting in the auriculo-ventricular instead of in the sino-auricular node occurs, but is uncommon.

Auricular flutter and auricular fibrillation are closely related, and in the same heart one may be transformed into the other, thus under quinidine fibrillation returns through impure and occasionally pure flutter to a normal rhythm (Lewis, Drury, Hlescu and Wedd). They are both due to circus movement in the auricles depending on shortening of the refractory period in the muscle fibres. But in auricular fibrillation the refractory period of the muscle is shorter, and as a result the path taken by the circus movement is shorter and more irregular than in flutter (Lewis 1921). The muscle fibres of the auricle contract independently of each other, and much more rapidly than in flutter. The auricle fibrillating at the rate of 450 times a minute overwhelms the conducting capacity of the auriculo-ventricular bundle, so that some only of the impulses reach the ventricle, and these are so irregular that the characteristic pulse results.

Quinidine sulphate and digitalis relieve the subjects of auricular fibrillation in different ways. Mackenzie showed the value of digitalis in auricular fibrillation while recognizing that it did not restore the auricular contractions, and Cushing and others proved that it acted by inducing a certain amount of heart-block. An enormous amount of experimental work has been done upon the action of digitalis on the heart of cold- and warm-blooded animals, the effects on the two being different. In the mammalian heart contractility and inhibition are increased and then conduction is impaired. The observations of Lewis and his co-workers upon the action of certain drugs upon fibrillation of the auricles, in 1922, showed that quinidine sulphate lengthens the refractory period, and so, by closing the gap between the wave and the advance of the circulating wave, tends to abolish auricular fibrillation but in addition it has the antagonistic effect of slowing conduction and so widening the gap between the successive waves. Successful treatment therefore depends on the first effect being predominant, and so enabling the normal pacemaker to regain control.

Paroxysmal tachycardia was described by Cotton (1867), called tachycardia by Gerhardt (1881), received its full title from Bouverot (1889), and was critically considered by Herringham (1897). The polygraph and the electro-cardiograph in Mackenzie's and Lewis's hands have thrown much light on this clinical syndrome, showing that it is not simply an acceleration of rate, but that the rhythm is abnormal as a result of the stimulus originating not in the sino-auricular node but elsewhere. The ectopic stimulus may start in the auricle, so that transient attacks may

be due to accelerated nodal rhythm (Lewis), to auricular flutter, to auricular fibrillation, or may even originate in the ventricle.

PHYSIOLOGICAL AND PATHOLOGICAL EVIDENCE

Essential in all branches of medicine, in none, except perhaps in neurology, has experimental physiology been more inseparably connected with progress than in the cardio-vascular system. Clinical observation alone, though in the hands of the greatest intellects, has laboured long and often ineffectually, but when aided and corrected by experimental control has rapidly brought about an advance in cardiological knowledge. This difference in the results given by these two ways—clinical observation and experiment—of obtaining new knowledge in medical science, which is so disappointing to the pure clinician that he may not unreasonably contest the statement, depends on the inherent potentialities of the two methods. In clinical observation the conditions cannot be arranged to meet the exact requirements as can be done in a laboratory. The clinical ward has been called "the physician's laboratory," but obviously this phrase does not confer the same opportunities for exact determination of questions as are provided by the experiments of the physiological laboratory. On the other hand, some care must be taken in transferring the results on animals to the more complex conditions in man. As disease, according to Claude Bernard's definition, is a physiological reaction in altered circumstances, it is obvious that the laws of these reactions can be much more surely established and the modifying circumstances varied and controlled by well-considered animal experiments. Further, animal experiments prepare the way for the application of somewhat similar methods to man—thus Stephen Hales's experiments on blood pressure find their clinical representatives in the modern sphygmomanometers. Marey's tambours and Mackenzie's polygraph, the observations of electrical changes in muscular contraction eventually led up to the electrocardiograph. Gaskell proved that the cardiac contractions arise in the muscular tissue independently of the nerves and ganglia, and that the auricles and ventricles have their own automatic rhythm, though normally obedient to the influence of the sinus. This was to some degree fore-shadowed by Harvey's observation that if the ventricle of an eel or of various fish is cut into several pieces contractions continue in the several portions. It must not be forgotten that the recognition in 1672 of muscular irritability by Harvey's fellow countryman, Francis Glisson, which was revived by Albrecht von Haller, who in 1757 stated that the cardiac contractions originated in the muscle, was the first step in the recent elucidation in Gaskell in physiology and in pathology by Lewis and others of cardiac problems.

Although in his second letter to Riolaui in 1649 Harvey showed that he was familiar with local disturbances in the character of the cutaneous circulation it was not until long after the great conception of the circulation as a whole was established that its local characters received special consideration. The effects of embolism, studied by Viechow (1846-56) and independently in this country by W. Sewallhouse Kirkes (1852), led, from the resulting lesions, to the realization of end-arteries in the kidney and brain on the one hand, and on the other hand to the recognition of the peculiarities of the circulation in the spleen, lung, and liver, the two last having nutrient arteries (bronchial and hepatic) in addition to the vessels (pulmonary artery and portal vein) conveying blood to be modified in those viscera.

Nearly fifty years ago Roy pointed out that the splenic circulation differs from that of other organs in the important particular that the force which drives the blood through the organ is not the arterial blood pressure, but chiefly, if not exclusively, the rhythmic contraction of the muscular fibres in the splenic capsule and trabeculae. Barcroft's observations suggest that in the spleen there are alternative circulations, and that the blood of the large splenic artery may either (1) when not required elsewhere, as it is in the emergencies of exercise or haemorrhage, accumulate in the splenic pulp, there to undergo changes, or (2) rapidly traverse a by-pass, and incidentally, like

the bronchial arteries to the lungs and the hepatic artery to the liver, maintain the nutrition of the viscus. The blood stored in the spleen may contain as much as a quarter of the red cells, and, as shown by Barcroft's experiments with CO poisoning, be practically cut off from the general circulation, and so remain free from a poisoned state ruling elsewhere. Anoxaemia stimulates the smooth muscle fibres in the spleen and so drives out the resting blood, it thus, as Henry Gray (1854) pointed out, regulates the quantity and quality of the circulating blood. While serving as a reservoir the spleen also acts as a metabolic refinery for the red blood cells and a manufactory for the white cells. The resting blood in the spleen deposits any foreign matter, such as bacteria, protozoa, and cells of malignant growths, which may either be destroyed the process being an immunological asset, or remain and by multiplying there account for the splenomegalies of chronic diseases, such as malaria, kala-azar, "splenic anaemia." As an important storehouse of reticulo-endothelial cells the spleen is concerned with the destruction of the red blood corpuscles, increasing their fragility by what Botazzi (1895) called its haemokatalytic function, and plays an important part in the first stage of the transformation of effete haemoglobin into bilirubin.

Weaver's even more recent evidence that the blood in the coronary arteries has alternative circulations, either through the capillaries into the coronary sinus, as usually considered, or directly into the Thebesian or other veins and so into the cardiac cavities, is of obvious importance in connexion with angina pectoris.

These data have a bearing on the question of the reserve power of the organs, which in the past has been regarded as mainly or entirely quantitative in character. Now it would appear that the reserve power may also depend on the utilization of potential alternative courses of the circulating blood, and that in pathological conditions compensatory processes may maintain the reserve of an organ, as has been mentioned in the case of the heart in coronary obstruction, and is perhaps also shown in the increased size of the hepatic artery in cirrhosis of the liver. The variations in the state of the capillaries—full or empty—in different areas of the body, which Thomas Young clearly anticipated in his forgotten Croonian Lecture before the Royal Society in 1810, have been recently brought out by the work of Krogh, Lewis, Drile, and others.

A more accurate knowledge of the unit blood supply of the kidney and liver is important so as to understand the mechanism and distribution of changes likely to result from blood-borne toxæmias or septicaemias and from chronic vascular disease. With the help of x rays and radio-optic injection mass, normal and pathological kidneys have been investigated, with results encouraging as regards further knowledge about differences between arterio-sclerotic and glomerular nephritis (R. S. Graham).

The coronary arteries are provided with vaso-constrictor nerves from the vagus, and vaso-dilator from the sympathetic (Auer). Adrenaline undoubtedly dilates the coronary arteries of animals usually employed in laboratory experiments, accordingly Büdinger, at the suggestion of Morawitz and Zohn, treated cases of angina pectoris with hypodermic injections of adrenaline, but the results were negative. Barbour (1912) found that the action of adrenaline causes vaso-constriction of rings of human coronary artery thus differing from its effects in laboratory animals, and with Prince showed that in the monkey this difference also holds good, the coronary arteries of these two species being presumably supplied with constrictor fibres from the true sympathetic. Reference has already been made to Weaver's observations on the alternative courses in the coronary circulation.

Pulmonary Circulation.—The questions whether or not the branches of the pulmonary artery (1) are under the control of the vasomotor nerves, and (2) are acted upon by drugs in the same manner as the systemic vessels, are obviously of practical importance in connexion with the causation and treatment of haemoptysis and pulmonary oedema. The need of an authoritative lead from physiology on these points was very clearly expressed by James Andrew in his Harveian Oration of 1901. Vasomotor innervation of the pulmonary vessels was

denied until 1871, when C L Brown-Séquard, on experimental grounds, argued that lesions of the pons caused haemorrhages, and injuries of the medulla oblongata oedema of the bases of the lungs as a result of impulses transmitted through branches of the sympathetic leaving the cord in the upper dorsal region. Rose Bradford and Dean (1889, 1894) found that in the dog vasomotor nerve fibres derived from the upper dorsal nerve supply the pulmonary blood vessels, though the pulmonary vasomotor mechanism is poorly developed as compared with that regulating the systemic arteries. They also concluded that the pulmonary circulation is comparatively independent of the systemic, and that alterations in the blood pressure of the latter must be so considerable as to interfere with the action of the cardiac valves and produce regurgitation before affecting the pulmonary blood pressure. On the other hand, Brodie and Dixon, in 1904, denied the vasomotor control of the pulmonary circulation, and in 1928 Dixon and Hoyle confirmed this. In the meanwhile Fühner and Starling, using the heart-lung preparation, found a considerable degree of pulmonary vasoconstriction and a rise of pulmonary arterial pressure with adrenaline, and in 1905 François-Franck came to a similar decision. In a critical review of the extensive work on the subject Wiggers, in 1921, concluded that reflex vasomotor effects on the pulmonary circulation must be regarded as probable rather than proved.

The intracranial circulation is remarkable for the rigid cranial cavity and the water-bed of the cerebrospinal fluid. Whether or not the nerves accompanying the cerebral vessels exert a vasomotor function has been repeatedly investigated, but with discordant results. Roy and Sherrington (1890), L Hill (1896), and more recently Florey (1925) who found that the cerebral arteries and the cerebral ends of the capillaries react to mechanical, thermal, electrical, and chemical stimuli by contraction and dilatation, agree that there is not any evidence of nervous

control over the cerebral vessels. On the other hand, the existence of active functional control of the cerebral vessels by vasomotor nerves has been supported by Claudio Bernard (1858), Notthnagel (1867), Wiggers (1915), Forbes and Wolff (1928), and others. The experimental observations are of much interest in connection with the belief held by many clinicians that transient paralyses, such as occur without evidence of a gross lesion, may be due to spasm of the cerebral arteries analogous to that in Raynaud's disease. Osler (1911), in describing transient attacks of aphasia and paralysis in states of high blood pressure and arterio-sclerosis, accepted the view put forward by Peabody (1891), W Russell (1909), and others that they were due to transient spasm. Florey has thrown out the suggestion that possibly in pathological conditions, such as arterio-sclerosis, an abnormal metabolic product which has not any effect on normal blood vessels may produce spasm of damaged arteries.

The influence of the conditions of the cerebral circulation on the general blood pressure has been much discussed. Starling and Anrep (1925) showed that when imperfectly supplied with blood the vasomotor centre brings about a compensatory rise of blood pressure, thus confirming Cushing's earlier demonstration in 1901 that the vasomotor centre exerts a regulating influence whereby anaemia of the medulla oblongata is prevented when the intracranial pressure is increased above that in the cerebral vessels. This was supported by Bordley and Baker's (1925) observation that in arterio-sclerosis a high blood pressure was definitely associated with sclerosis of the arterioles of the medulla; this however, was contested by Keith, Wagener, and Kernohan, and Cutler's observations showed that gross vascular changes in the blood supply to the medulla were not responsible for blood pressure changes. Experimentally Florey, Marvin, and Drury (1928) found that lowering the blood pressure in the circle of Willis has not any influence upon the general blood pressure.

ON RECOVERY FROM SYMPTOMS OF INTRACRANIAL TUMOUR

BY

C O HAWTHORNE, M D GLASC, F R C P,
F R F P AND S

CONSULTING PHYSICIAN HAMPSHIRE AND NORTH WEST LONDON
GENERAL HOSPITAL AND CENTRAL LONDON OPHTHALMIC
HOSPITAL

THAT an intracranial tumour can exist without distinctive symptoms, and even without suggestive symptoms, is a proposition that has for its warrant the sure teaching of experience. Again, it is well recognized that even when symptoms of tumour are present there is often, in the course of one and the same case, a wide variation in the degree of their severity, and, indeed, a period of quiescence may be so prolonged and so pronounced as to cast suspicion on the accuracy of the diagnosis. The explanation of such experiences is that for the most part the symptoms associated with intracranial tumour are due less to the mass of the tumour than to circulatory disturbances (congestions, anaemias, oedemas, haemorrhages, softenings) liable to occur in its neighbourhood, and to interferences which the tumour may exercise on the circulation of the cerebrospinal fluid. Grant the absence of these accidents, and cerebral events and symptoms, in spite of the presence of a tumour may be slight, non-suggestive and even non-existent.* With these positions admitted, may it not be possible that symptoms, and even pronounced symptoms, of intracranial tumour may disappear, not merely for a more or less brief period, but completely and permanently? For if in an individual case the intracranial accidents or complications, and the symptoms which result from these, may after a period of activity subside, the possibility that such quiescence may be permanent can at least be contemplated. Assume that the tumour ceases to grow or perhaps shrinks in size, and that in this or in some other fashion it no longer causes the intracranial disturbances on which the

clinical evidences of tumour mainly depend, and it is no violent proposal to suggest the possibility of a clinical record in which the symptoms of intracranial tumour disappear completely and the patient regains a level of good health. The clinical history unfortunately, marches usually in the opposite direction, but there is nothing in the nature of things to render exceptions to this rule impossible, and the principal object of this communication is to suggest that such exceptions do actually occur. This suggestion has for its support case records (admittedly exceptional) marked in the earlier stage by symptoms regarded as conclusive of intracranial tumour, while later these symptoms disappear and the patient succeeds to good health. Such experiences, of course, call for an explanation, and the explanation here proposed is cessation of intracranial disturbances consequent on quiescence or shrinking of the tumour growth.

That recovery from symptoms of intracranial tumour, except for blindness due to optic atrophy, actually occurs there can be no doubt. Records of patients who in earlier years have suffered a severe illness characterized by headache, vomiting, and optic neuritis, and who, but for loss of sight, have later made a good recovery, are well established. It may be suggested that these cases are not cases of tumour, and it must be admitted that in exceptional instances the symptoms just quoted have existed and yet no tumour has been found on *post-mortem* examination,¹ such conditions as hydrocephalus,² serious meningitis,³ or sinus thrombosis⁴ may perhaps be advanced as alternatives to tumour. On the other hand, in many patients who are blind from optic atrophy after an illness distinguished by cerebral symptoms, competent clinical observers present at the time of the original illness have felt no doubt that the symptoms meant intracranial tumour and now and again in the brain of a patient included in this group and dying years after the primary illness, a tumour has been present to *post-mortem* demonstration. Thus it is certain that within the natural history of intracranial tumours room must be found for cases in which all active evidences of the presence of a tumour disappear, the former cerebral disturbances being

* A recent example is reported by Professor Sydney Smith *British Medical Journal* January 22nd 1927.

indicated only by blindness due to optic atrophy consequent on the earlier double optic neuritis. Clinical records of this order can be found in the writings of Jonathan Hutchinson, Hughlings Jackson, and others, and some years ago I published a detailed study of a number of such cases.¹

The usual story is of a severe and more or less prolonged illness which occurred in early life and was followed by recovery qualified by blindness, and examination shows atrophic optic discs. In some instances this is all, while in others there are, in addition to the blindness, such other evidences of cerebral disturbance as ocular or facial palsies, unilateral motor weakness, abnormalities of the tendon jerks or of the superficial reflexes. Again, some of these patients are liable to quasi-epileptic seizures or to mental instability, and individual instances have been noted in which, after a more or less prolonged period of good health, active and alarming symptoms of cerebral disturbance have recurred, followed by death or occasionally by a second recovery. The immediate point relative to the present argument is that after an illness having symptoms which suggested or even compelled the diagnosis of intracranial tumour, the patient, but for blindness the result of consecutive optic atrophy, may apparently get quite well and may remain well for years. Every now and again such an experience is described in the medical journals, and more or less numerous examples have been collected by the authorities already quoted. Two recent cases may be summarized as illustrations.

CASE 1

Thos W aged 65 admitted to hospital with left-sided pleurisy. He is blind and the optic discs are conspicuously atrophic. His loss of sight is attributed to a serious illness which lasted for two years when he was 8 to 10 years of age, with this exception he has had good health.

CASE 2.

Ellen C aged 45. When 18 she had "a heavy illness" of some twelve months duration and characterized by headache, vomiting and double vision. Since this she has been blind but has had fair general health interrupted occasionally by headache. Examination shows consecutive optic atrophy and paralysis of the left external rectus, but no other evidence of disease.

In Case 1 recovery is complete but for optic atrophy, in Case 2 there is, in addition to the optic atrophy, an ocular paralysis and some recurrence of headache. A *post-mortem* demonstration that cases such as these are really cases of intracranial tumour cannot often be obtained. Yet even this degree of evidence is not altogether wanting, and records of a few such cases have been completed by the discovery of a tumour at the *post-mortem* examination. A very impressive experience of this order is described by J R Lunn²—namely

CASE 3

A man, aged 27, was admitted to Marylebone Infirmary in October, 1887, with a story of failing eyesight and severe headaches since Christmas, 1886. The left eye was quite blind and the disc pale, the right eye was nearly blind and receding optic neuritis was present. He lived for seventeen years in the infirmary without symptoms of active disease except on two occasions a 'fit' attended by unconsciousness, he died after a similar seizure in 1904. *Post-mortem* examination disclosed a fibrocytic tumour the size of a pigeon's egg in the interpeduncular space and involving the optic chiasma.

A parallel case is recorded by Professor T K Monro.³ The patient was blind for thirty-seven years after the original illness, a myxomatous tumour was found in the cerebellum. In another instance, described by Dr Lloyd Roberts,⁴ there was, eight months after recovery from the original illness, a recurrence of the cerebral symptoms, followed by death, but in the interval the patient, though blind, had been "perfectly well." *Post-mortem* examination discovered a glioma of the cerebellum.

From such experiences it is manifest that an illness accompanied by severe cerebral symptoms, including bilateral optic neuritis, and followed by disappearance of all the symptoms except blindness due to optic atrophy, may have as its explanation the existence of an intracranial tumour. Presumably the tumour shrinks or ceases to grow and so no longer causes the circulatory and allied disturbances which are the immediate causes of the clinical symptoms associated with intracranial tumours. The proposal now made is that in rare instances this cessation of tumour activity may be accompanied, not only by cessation

of headache, vomiting, and the rest, but also by subsidence of the optic neuritis without damage to the optic nerve fibres, and consequently without prejudice to vision. In support of this proposition there are here submitted six case summaries—namely, one in which optic neuritis disappeared for some three years and then recurred, and the *post-mortem* examination revealed an intracranial tumour, one where the optic neuritis and other symptoms disappeared under antisyphilitic treatment, and four examples of complete recovery from symptoms (including bilateral optic neuritis) regarded by experienced observers as indicative of intracranial tumour.

CASE 4

A man (F W), aged 62 when first seen in 1916 had suffered for four years from occasional "giddy attacks," and in some of these had fallen to the ground, but had never lost consciousness, there were no objective signs of disease and no optic neuritis and an aural surgeon reported nothing beyond slight dry catarrh in middle ear. At the end of 1917 "attacks" had continued, and there was definite exudation at the right optic disc and some blurring of the edge of the left disc, the Wassermann test of blood and cerebro-spinal fluid was negative. In March 1919, he reported himself as much better, general examination was quite negative and the optic discs were regarded as normal. Early in 1920 he had a severe "attack" of giddiness with apparent unconsciousness (no convulsions) lasting some fifteen minutes. There was extreme optic neuritis in the right eye, loss in the left. The skull was trephined, but the patient died a few days after the operation, a firm fibrous tumour the size of a large cherry was adherent to the right petrous bone.

The feature of the case particularly relevant to the present communication is the disappearance, for a time at least, of the optic neuritis without damage to vision, though, as shown by the subsequent facts, the neuritis was undoubtedly caused by an intracranial tumour.

CASE 5

A woman (A H) aged 27, was admitted to hospital with a history (three months) of severe headache, vomiting and recently of double vision. Vision was 6/12 in each eye. There was extreme swelling of each optic disc, and paresis of the external rectus of the left eyeball. The Wassermann test was positive. Examination showed nothing abnormal in other respects. There was prompt improvement under treatment. Seen two years later she was in good health, the optic discs were whitish, with traces of former exudation, vision (each eye) 8/6.

The disappearance under appropriate treatment of clinical signs of intracranial specific disease is, of course, a familiar experience. But in the present series Case 5 takes its place as a proof that optic neuritis due to an "adventitious product" within the skull may disappear when the activity of the intracranial cause is reduced, and also, that optic neuritis so removed may leave vision intact. If this is true when the "adventitious product" is a specific mass, may it not be true also of other pathological masses—for example, tuberculoma? The three records quoted under "Case 3" would seem to give an affirmative answer.

CASE 6

A woman (Mrs T) aged 46, seen with Dr Gavin Barbour in October, 1920. She had complained for six months or so of severe headache which often prevented sleep and recently of dimness of vision, no vomiting. There was extreme exudation at each optic disc, no other objective sign of nervous disease was present and the blood serum and cerebro-spinal fluid gave a negative Wassermann reaction. In 1922 the patient reported herself well, the optic discs were white but there was no swelling. Vision right eye 6/6, left 6/18 (extreme myopic astigmatism). 1928 well, and active social worker.

Whether this is or is not a case of tumour, the record certainly shows that a severe degree of exudation at the optic disc (regarded as due to tumour) may be absorbed and vision be left unimpaired.

CASE 7

A woman (E C) now (1928) aged 35 was from May to August, 1903 an inpatient in the National Hospital, Queen Square with a history of attacks of pain in the head, giddiness and vomiting extending over two years. There was considerable exudation at each optic disc. Vision each eye (with myopic correction) 6/9. The case was indexed as 'intracranial tumour infratentorial (?) left cerebellar'.⁵ The symptoms ceased (except for one attack) during residence and the patient was instructed to return should there be any further attacks.

March 1st, 1921. Seen with Dr R D Bell of Luton. The patient had worked as a milliner since leaving the hospital, she had occasional headaches and in 1915 was ill for six months with attacks of pain in the head, giddiness and vomiting, she recovered and was at work again until two months ago when headache and giddiness were again troublesome, the optic discs

* I am indebted to the courtesy of Dr Macdonald Critchley, the medical registrar, for the opportunity of seeing the original notes.

looked suspicious but were not swollen no suggestion of atrophy vision (with glasses) 6/9 each eye no contraction of visual fields. In other respects there were no signs of organic disease.

August 31st 1928 Patient attended for examination by request. She was able to continue to work and examination showed her general condition and the ophthalmoscopic facts to be the same as in 1921.

In a word, a patient regarded in 1908, and by an experienced physician, as undoubtedly the subject of an intracranial tumour, is in 1928 in fair general health, and the former optic neuritis has disappeared without leaving optic atrophy as its sequel.

CASE 8

A boy (J L) aged 9 years seen with Dr Meikle in February 1924 gave a history of attacks of severe headache sometimes attended with vomiting extending over three months recently diplopia and dimness of vision and weakness of the left upper limb. Examination showed much exudation at each optic disc vision (each eye) 6/9 part paresis of the right external rectus and of the left lower face. He was admitted to hospital with a view to operation but gradually the headache and vomiting ceased, double vision disappeared and there was obvious recession of the swelling of the optic discs. In the end the boy left the hospital apparently quite well. Seen in November 1925 his weight had increased from 5st. 1lb to 7st. 7lb his mother described him as in perfect health. Examination was negative except that the optic discs were unduly white vision (each eye) 6/6. In August 1928 Dr Meikle reports him to be perfectly well.

In the early stage of this case there seemed no possible escape from a diagnosis of intracranial tumour. Does the completeness of the recovery and the persistence of good health qualify this conclusion? If not, then the case illustrates the proposition advanced in this communication—namely, that recovery from symptoms of intracranial tumour, when it occurs, may proceed to such a level as to include resolution of an optic neuritis and retention of a full standard of vision.

CASE 9

A boy aged 6 was seen in May 1894 by Mr Charles Higgins on account of failure of sight vision was found to be much depreciated there was exudation at each optic disc. He was later seen by Dr (afterwards Sir David) Ferrier who recognized double optic neuritis and symptoms of cerebellar disease and regarded the case as one of tumour. After this the boy was reported to have gone blind but when re-examined in 1907 by Mr Higgins the visual acuity in each eye was 6/6 and the optic discs though pale were otherwise normal.

When these case records are subject to examination as a whole it would appear that in Cases 1, 2, and 3 symptoms of intracranial tumour disappear except for blindness due to optic nerve atrophy, while in Cases 6, 7, 8, and 9 similar symptoms are followed by complete recovery and the reliability of the recovery is certified by freedom from symptoms for a term of years. Except in the degree of recovery attained, there does not appear to be any reason to draw a distinction between the two groups and Cases 4 and 5 may be quoted as emphasizing the identity of the pathological basis on which the several cases rest. Hence it would appear that the facts as here collected and quoted justify the following conclusions:

1 That headache vomiting, and allied symptoms indicative of intracranial tumour may cease the patient however remaining blind from optic nerve atrophy (Cases 1 and 2).

2 That in some of these cases post mortem examination years after the original illness has shown the presence of intracranial tumour (Case 3 References 7 and 8).

3 That in cerebral syphilis (presumably gumma) all the symptoms including optic neuritis, may disappear leaving the patient with normal vision (Case 5).

4 That similarly, in occasional cases—non syphilitic—symptoms of intracranial tumour including optic neuritis may disappear leaving the patient with normal vision (Cases 6, 7, 8, and 9).

5 That whilst it is no doubt generally true that success in operations for intracranial tumour would be promoted by earlier diagnosis the possibility of the natural subsidence of even pronounced cerebral symptoms might not be forgotten.

VITAMIN A AS AN ANTI-INFECTION AGENT

BY

H. N. GREEN, M.D., Ch.B., M.Sc.,

AND

L. MELIANY, M.D., F.R.C.P., F.R.S.

(From the Pharmacology Department University of Sheffield.)

THE assigning of names descriptive of some particular function to distinctive vitamins has been a useful, although probably only temporary, step in the development of knowledge of these elusive entities, because their identification has so often depended upon the appearance of definite syndromes in animals whose diets have been deficient in certain respects. The use of the words "antiscorbutic," "antirachitic," and "antirachitic" in describing specific vitamins is an example of this, and from a clinical standpoint the nomenclature has been of great value. Vitamin A has always presented special difficulties to a clinically descriptive term because it has depended to such a large extent on a purely physiological criterion—namely, growth in young animals—for its detection. It is in consequence often referred to as the "growth-promoting" vitamin. Since the recognition of vitamin D (the antirachitic vitamin) as an entity distinct from vitamin A, those with experience of nutritional work have felt that to call vitamin A the "growth-promoting" vitamin is a misnomer, for good growth often takes place in its absence if the diet is otherwise complete. In fact, when growth ceases owing to the single absence of vitamin A from the diet, it often means that the animal is definitely ill—in the sense, as will be seen below, of its having developed some, and often a widespread infective condition. Indeed, the present paper supplies evidence in favour of the term "anti-infective" being applied to vitamin A.

From the early days of its recognition it has been thought that vitamin A was concerned with resistance to infection at least of a specific type. This is seen in its description as the "anti-xerophthalmic" vitamin but this appellation has never become widely adopted, partly because xerophthalmia in human beings, although related to vitamin A intake as suggested by the observations of Mori¹ and shown by Bloch,² is of very rare occurrence and partly because McCollum, Simmonds, and Becker³ have shown that this eye condition results from dietetic abnormalities other than vitamin A deficiency.

Several workers, including Drummond,⁴ Cramer and Kingsbury,⁵ and Steenbock,⁶ have commented on the susceptibility to lung infections of animals on vitamin A deficient diets. In the case of dogs E. Mellinby⁷ drew attention to the development of broncho-pneumonia in animals living on diets deficient in fat soluble vitamins. He pointed out that this tendency to broncho-pneumonia was independent of the condition of the bones, which is itself an indication of the vitamin D intake. For instance, when cod-liver oil was present in the diet the bones were well calcified and there was no tendency to broncho-pneumonia or atelectasis of the lungs. When butter-fat was the source of fat-soluble vitamin, the bones under certain experimental conditions were soft and portions of the lungs were often in a collapsed state, probably because of muscular paresis, but there was no broncho-pneumonia or other infective condition. When olive oil replaced butter, badly calcified bones, collapse of portions of the lungs, and broncho-pneumonia were commonly found. These results suggested that protection against infection of the respiratory tract was conferred by vitamin A and not by vitamin D.

Linked up with the problem of xerophthalmia and other infective conditions is that of the changes in epithelium induced by diets deficient in vitamin A. The first to draw attention to these epithelial changes was Mari⁸ in 1922, who described them in the larynx, trachea, and ducts of many glands including the Meibomian, submaxillary sublingual, and parotid glands of rats. Xerophthalmia he regarded as being due to the drying of the epithelium resulting from the suppression of activity of the lacrimal glands. Wolbach and Howe⁹ extended this work of Mari's

and described changes in the pancreatic duct and renal pelvis. They gave a detailed description of histological changes in epithelium, and came to the conclusion that infective changes are not responsible for the epithelial hypoplasia and keratinization, but are secondary to them. The diets used by Mori, and those of Wolbach and Howe, were deficient in vitamins C and D as well as A, but these other deficiencies were not regarded by them as affecting the problem.

This complication was eliminated by Goldblatt and Benischek,¹⁰ who tested the effect of a simple vitamin A deficiency. By this means they induced metaplasia of

columnar, cuboidal, and transitional epithelia to the squamous keratinizing type. When vitamin A was present no changes in the epithelium were observed. In the course of their work they found on making *post-mortem* examinations many cases of infection in animals which had lived on diets deficient either in vitamin A or vitamins A and D. These infective conditions included xerophthalmia, abscess of tongue, abscess of submaxillary glands, broncho-pneumonia, and enteritis. Abscesses beneath the tongue are of interest because of their frequency. They were first described as resulting from a vitamin A deficiency by Sherman and Munsell.¹¹

A striking instance of epithelial hypertrophy and keratinization is that described by Fujimaki¹¹ at the cardiac end of the rat's stomach, induced by diets deficient in fat-soluble vitamin. This hypertrophy he described as cancerous, and certainly, when the centre of the swelling becomes infected, the appearance of the mass is very suggestive of cancer, although, in our experience, microscopic examination does not reveal malignancy.

Another morbid development related to vitamin A deficiency is that of infection of the genito-urinary tract, and the occasional appearance of stones in the bladder and less often of stones in the pelvis of the kidney. The production of stones in the bladder was first described by Osborne and Mendel,¹² and although this was at one time denied by McCollum¹⁴ as being due to vitamin A deficiency, the observation has been confirmed by Fujimaki¹⁵ and Van Leersum.¹⁶ Van Leersum found the stones to be usually composed of calcium phosphate, but occasionally they consisted of calcium oxalate.

McCarrison¹⁷ has also observed stone in the bladder of rats brought up on diets deficient in fat-soluble vitamins. A point of interest about his basal diet is that he included either oatmeal or atta (whole meal) in large quantities among the substances eaten. Since 1922 we¹⁸ have emphasized the special demand on fat-soluble vitamins made by cereals, and especially oatmeal, and this may be another instance of cereal and vitamin antagonism.

In view of the fact that practically all the experimental work except that of Goldblatt and Benischek¹⁹ has been complicated, in that the diets were deficient in both vitamins A and D, and often C, it was felt desirable to repeat the work with the special object of seeing why diets deficient only in vitamin A result in the death of animals eating them. The production of vitamin D by irradiation of ergosterol, as described by Rosenheim and Webster²⁰ and Windaus and Hess,²¹ made it possible to give diets deficient only in vitamin A. The results obtained confirm those above described, but the animals eating these diets were so uniformly attacked and ultimately killed by infective and prostatic complications as to make the investigation singularly impressive from a medical standpoint. It is, in fact, difficult to avoid the conclusion that an important, and probably the chief, function of vitamin A from a practical standpoint is as an anti-infective agent, and that a large number of common infective conditions are due to a deficiency of this substance in the diet of many people.

EXPERIMENTAL METHODS AND RESULTS

The composition of the basal diet used in these experiments was as follows:

Heated casein	400 grams
Rice starch	800
Salt mixture	80
Cane sugar	240
Marmite	160
Olive oil	160 c cm
Lemon juice	140
Liquid salt mixture	160

The liquid salt mixture had the following composition:

Calcium acid phosphate	176 grams
Potassium iodide	10
Water	2 000 c cm

The salt mixture was as follows:

Sodium chloride	92 grams
Magnesium sulphate	142
Sodium phosphate	185
Potassium phosphate	509
Calcium lactate	694
Ferric citrate	63
Sodium fluoride	1 gram
Manganese sulphate	4 grams

The casein was beaten in an electric oven for thirty-six hours at 120° C. The olive oil varied, in some cases it was omitted from the diet, in others it was given either unheated, or heated and oxygenated for periods of either six or twelve hours at 120° C. As this variable made little or no difference, so far as could be seen, to the outcome of the experiments, it will not be considered further. Vitamin

D was given in the diet in the form of irradiated ergosterol (radiostol 1/2 to 1 drop per rat daily). The age of the rats when the diets were started varied between 26 and 35 days, and their weights ranged between 35 and 50 grams.

In the control experiments where a source of vitamin A was included in the food, 0.5 gram of dried cabbage (dried at a temperature of 70° to 80° C for twenty hours) was generally added, and in other cases either butter (0.1 gram daily) or cod-liver oil (5 to 10 mg daily) was used as a source of vitamin A. In a few experiments which belong to another investigation other substances deficient in vitamin A have been fed to the rats, and the results are recorded in the tables. These included vegetable margarine, heated wheat germ, and ergot. The amount of vitamin A in these substances in the quantities given is negligible, but, as we have recently shown, ergot is a rich source of vitamin D.

I—Post-mortem Findings in Animals Fed on Vitamin A Deficient Diets

In the accompanying tables infection is indicated by +. The extent and intensity of infection in the case of xerophthalmia and tongue only are indicated by the number of + marks in each case.

TABLE I (b)
A Deficiency Basal Diet + Vitamin D + Vegetable Margarine

Rat No	Sex	Days on Diet	Xeroph	Tongue Abscess	Alimentary Infection	Other Sites of Infection
151	M.	46 Margarine			+	
316	F	70 Margarine		+		
341	F	41 Margarine			+	
305	V	86 Margarine			+	Nasal sinuses
337	F	19 Margarine	+		+	
348	M.	76 Margarine		++		
329	F	113 Margarine	+	++		Middle ear nasal sinuses

There was no kidney infection bladder stone or bladder infection in any of the animals in this group.

II—Post-mortem Findings in Animals Living on Diets Deficient in Vitamins A and D

TABLE II (a)—A-Deficiency Basal (no Vitamins A or D)

Rat No	Sex	Days on diet	Xeroph	Tongue Abscess	Alimentary Infection	Kidney Infection	Bladder Stone	Bladder Infection	Other Sites of Infection
RO				+	+

TABLE II (b) —A-Deficiency, Basal (No Vitamins A or D)
+ other Substances

Rat No	Sex	Days on Diet	Xeroph	Tongue Abscess	Alimentary Infection	Kidney Infection	Bladder Stone	Bladder Infection
230	M	69 Heated wheat germ		+				
287	F	89 Heated wheat germ		+	+		+	+
81	F	83 Fat-extracted wheat germ						
68	M	47 Ergot (50 mg.)				Stone		
266	F	55 Ergot (50 mg.)	+++		+	Stone	+	
271	M	57 Fat-extracted ergot (100 mg.)						
272	F	83 Fat-extracted ergot (100 mg.)		++		Stone		

The wheat germ used in experiments 286 and 287 was heated for twelve hours at 120°C. Ergot used in 266 and 266 contained vitamin D but the fat-extracted ergot of experiments 271 and 272 was free from vitamin D. The nasal sinuses were infected in rat No 281.

The regularity with which stone in the pelvis of the kidney appears in animals whose diets contain ergot suggests that this substance plays some part in the development of the condition. It will be noticed that, without ergot, although infection of the kidney is common, stone in the kidney is rare. In other experiments, besides those given above, stones or gravel have been found in the renal pelvis when ergot has been a diet constituent.

ADDITIONAL DETAILS OF POST MORTEM EXAMINATIONS OF A FEW OF THE RATS OF VITAMIN A DEFICIENT DIETS

Rat 313—Tongue Left kidney twice normal size. Medulla replaced by pus so that only a thin strip of cortex remains. Left ureter extremely dilated being almost a quarter of an inch wide at its junction with the pelvis. Stone impacted at lower end. Right kidney enlarged, numerous necrotic areas in cortex, advanced pyelonephritis. Large quantity of necrotic epithelial debris in bladder.

Rat 284—Abscess of tongue involves most of tongue and has perforated on to the upper surface. Larynx contains a little pus. Kidneys slightly enlarged (more so left), white mottling of cortex, particularly marked in left kidney, slight pyelonephritis in both kidneys. Abscess in prostate glands. Large quantity of pus in both middle ears.

Rat 292—Tongue abscess. Marked xerophthalmia, pus in the anterior chamber of the right eye. Stomach contains dark brown blood. Pyloric mucosa inflamed. Both kidneys much enlarged, lower pole of right kidney almost reaching brim of pelvis, cortices mottled particularly marked in right kidney, great distension of the pelvis, which contain white necrotic material. Ureters grossly dilated (size of large intestine), fine sand at the lower ends, the right being inflamed and containing a blood-stained effusion. Pelvis intensely congested. Coils of small intestine adherent to the right fallopian tube and bladder. Intestine acutely inflamed and contains blood-stained serum. Right side of pelvic floor inflamed being a mass of necrosed friable tissue with an abscess extending down to bone. Fallopian tubes show small white cavity extending down to bone. Fallopian tubes show small white cavity (similar to those seen in the kidneys, and probably necrotic) scattered on the outer surface. Right tube inflamed and adherent to the pelvic floor and intestine. Spleen enlarged. This rat had haematuria prior to death.

Rat 287—Stomach full of blood. Pyloric mucosa injected and showing haemorrhage into it. Left kidney slightly enlarged with semipurulent fluid in pelvis. Left ureter dilated. A large number of small stones and much epithelial debris at base of bladder. Two sessile red projections springing from bladder mucosa (granulomata or papillomata). Very large abscess in right sub-maxillary gland extending to level of first rib and upwards to the mandible. Chain of enlarged longitudinal glands on left side, some commencing to suppurate. Small abscess in either thyroid. Pus from abscess shows in film numerous Gram positive diplococci. Gram negative bacilli, and a few staphylococci and streptococci.

Rat 421—Large abscess of tongue extending almost to the tip and communicating with another large abscess underlying the left mandible. The tongue abscess has perforated and there is pus

in the larynx. Stomach full of altered blood, mucosa injected with numerous atreaky haemorrhages, petechial haemorrhages on outer surface of cardiac portion, and cardiac epithelium shows a curious circumscribed rugosity at the upper pole. Bladder small and full of a bright yellow sandy deposit (showing chiefly calcium oxalate crystals). Spleen shows on its surface numerous circular white foci (similar to those often seen in the kidney). Right epididymis intensely inflamed.

Rat 258—Severe enteritis (chiefly of jejunum). Small amount of altered blood in stomach. Pelvis of left kidney much dilated. Left ureter enormously dilated, the distal end being inflamed and filled with the same type of necrotic material as is found in the bladder. Right ureter moderately dilated. Bladder grossly inflamed, mucosa covered with shaggy masses of granulation tissue and necrosed cells which are very adherent, whilst papillomatous like masses are numerous. Abscess at base of tongue has perforated and formed an abscess in the mid line of neck overlying the larynx, and communicates with an external sinus. Left seminal vesicle enlarged and appears caseous. Abscess in left prostate. Nasal sinuses full of pus.

III—Control Animals—Basal Diet + Vitamin D (Irradiated Ergosterol) + Some Source of Vitamin A (Dried Cabbage or Butter or Cod-liver Oil)

Fifty rats of the same age and weight were kept for longer periods than the foregoing on diets which, while made up in the same way as those of the other experimental animals, contained some source of vitamin A, generally dried cabbage, but in some cases hutter or cod liver oil. No gross infective lesion was found in any of these animals, the only pathological findings discovered being three cases of hepatic cyst of parasitic origin.

DISCUSSION OF RESULTS

The fact that in practically all of the rats on a vitamin A deficient diet upon which a detailed *post-mortem* examination has been made some and generally many organs have been found to be infected by micro-organisms, is a most striking result. Under these conditions the animals live for fairly long periods, varying in the foregoing cases from 58 to 169 days. During most of the time they eat their food well and show moderate growth. It is only during the last week or so of the experiment that they fail to eat up their ration and lose weight in consequence. It appears as if they continue in fair health until the infective process gets the better of their general condition, and brings about loss of appetite and weight, and ultimately death. The evidence for infection was in every case macroscopic, being based either upon the presence of definite pus or of an acute inflammatory process. This meets the objection to deductions made only on the basis of histological observation, pointed out by Gross.⁶ Sometimes microscopic examinations of the tissues were made. In those cases in which bacteriological examinations of infected tissues and of pus were made no specific micro-organism was found, this result agreeing with that of other investigators. Gram-positive diplococci were often found, but these were usually associated with streptococci, staphylococci, and Gram-positive and Gram-negative bacilli. Occasionally the pus from infected glands of the neck showed a few chains of streptococci and no other organisms.

It will be noticed that the addition of vitamin D makes no great difference to the experimental results under discussion, for whether vitamin A only or both vitamins A and D are deficient the animals die with well-defined infective lesions. In fact, it often appeared that the addition of vitamin D in the absence of vitamin A hastened the onset of the infective condition. The reason for this is probably that the presence of vitamin D stimulated the rate of growth, and thereby made a greater call on the vitamin A stores of the body, thus hastening the diminution of resistance. There is no doubt that the stores of vitamin A in animals living on a diet devoid of this substance rapidly disappear. Evidence of this is seen in the tests made on the livers of deceased animals for the presence of vitamin A by the method described by Wilson.⁷—a method involving the use of the colour test of Rosenheim and Drummond²¹ as modified by Carr.²² Even in the case of rats dying at an early stage, and before any great pathological change had occurred, liver extracts gave negative

results, indicating the rapid using up of the initial stores of vitamin A in these rats. The control animals which received vitamin A in their food remained free from infection and all gave evidence, by the same test, of abundant quantities of the vitamin in the liver.

As regards the infective lesions that developed, it will be noticed that xerophthalmia was not so common as might be expected, only 38 per cent of the animals developing this lesion. It is, indeed, worthy of note that advanced lesions, even in old animals, were occasionally found at necropsy, although the animals showed no clinical signs of xerophthalmia.

In the 93 A-deficient animals examined the most characteristic condition was the lack of adipose tissue and the general visceral atrophy, but almost as prominent was the evidence of infection in some sites, only two animals of the 93 seeming to escape this.

Abscess at the base of the tongue, arising in the accessory salivary glands, was found in 72 per cent of the animals. In animals surviving for longer periods this figure rose to 90 per cent. These abscesses varied much in size, some being small caseous foci in the centre of the gland, while others involved almost the whole tongue, infiltrating it almost to the tip. Perforation of a tongue abscess was not uncommon. In one case a sinus communicated with the skin of the anterior surface of the neck, and in another perforation into a large artery resulted in death from haemorrhage. Associated with the tongue abscesses, suppuration occasionally occurred in the submaxillary glands and in the lymphatic glands of the neck. In some cases a chain of suppurating lymphatic glands was seen in the neck, the glands being usually quite discrete. The thyroids were involved in the suppuration in one animal.

Infection of the lungs was noticeably rare, only 9 per cent showing any definite signs, which were chiefly of a septic broncho-pneumonia. These cases all occurred during the winter months, though the temperature of the rat room was kept constant.

Infection of the alimentary tract was quite common, though in most cases it appeared as a terminal event, there being no clinical evidence of its occurrence. An acute inflammation of the small or large intestine occurred in 21 per cent of the rats. Many of these cases arose during an epidemic of enteritis in the rat room when, as previously mentioned, the vitamin A deficient animals proved to be very susceptible to the infection. In quite a number of animals an acute enteritis involving the duodenum and jejunum appeared to be the immediate cause of death. The intestine was grossly injected and filled with a copious haemorrhagic exudate. Usually there were signs of recent haemorrhage into the pyloric portion of the stomach.

Lesions of the urinary tract often dominated the scene in the abdomen. The occurrence of calculi—usually in the bladder, rarely in the kidney—was fully confirmed, but infection occurred independently of their presence or absence. 44 per cent showed evidence of infection either in the kidney or bladder, but the incidence was considerably higher in those rats surviving longer periods. The infection took the form of a pyelonephritis or cystitis, and sometimes pus was found in the kidney substance. The infection was usually associated with such conditions as hydrourephrosis, extremely dilated ureters, and a distended bladder. Multiple small white necrotic foci in the cortex of the kidney were often found, but their exact origin has not yet been determined. Similar foci have also been observed in the spleen on two occasions.

The prostatic glands and seminal vesicles were frequent sites of suppuration, whilst occasionally the epididymis was acutely inflamed or suppurating. A purulent exudate was seen in the Fallopian tubes on one occasion.

Pus was found in the nasal sinuses or in the middle ear on eighteen occasions, an incidence of 20 per cent. In one isolated case a small but definite abscess was found projecting from the wall of the left ventricle of the heart.

The control animals received the basal diet ad lib, plus some source of vitamin D, with the addition of a source of vitamin A either in the form of dried cabbage or cod liver oil or butter. Fifty rats fed under these conditions over periods as long as, or longer than, those which

the deficient rats survived have been killed and examined. In no single case was evidence of gross infection found corresponding with that found in the vitamin A deficient rats. The only pathological findings were three cysts of the liver, of parasitic origin. Otherwise all the tissues appeared perfectly healthy.

On the basis of these facts we suggest that vitamin A plays a significant part in raising the bodily resistance to infection. Perhaps this effect is solely due to the favourable medium which obstruction by desquamated keratinized cells provides for bacterial growth. At any rate, this must be a factor. Possibly it is the combination of the keratinizing process and a diminished resistance which makes animals with vitamin A deficiency so prone to infection.

The question arises as to what extent the part played by vitamin A as an anti-infective agent is specific. Would, for instance, the absence of any essential dietetic factor result in the infective and progenic conditions met with in this experimental work? We can offer no definite evidence that this is not the case, but an extensive experience of nutritional work suggests that vitamin A is more directly related to resistance to infection than any other food factor of which we are aware. In a series of several hundreds of rats which have had adequate amounts of vitamin A and little or no vitamin D only two cases of gross infection have been found, both septic broncho-pneumonias associated with definite rickets. Experience with scurvy in man and animals does not lead to the belief that vitamin C is concerned with infection in the same sense as vitamin A. Although, therefore, the specificity of vitamin A and infection is not settled, the evidence obtained is in its favour. We are endeavouring to obtain additional evidence on this point by experiments in which infective material is injected into animals on A-deficient and control diets.

Another point of importance is whether lack of vitamin A has any relation to the common suppurative processes found in man. Is it possible to relate inflammatory processes of the nasal sinuses, middle-ear disease, pneumonia, ulcerative conditions of mouth and eyes, to this dietetic deficiency? This question also cannot be answered definitely. It is certainly possible that there is a close relationship, since it is generally agreed that a deficient intake of vitamin A is a common fault among civilized man. We rely almost entirely on milk, butter, egg-yolk, and green vegetables for our supply of this substance, and the consumption of these, especially among the poor, is notoriously low.

We feel that, until further knowledge is gained, the experimental results are sufficiently impressive to warrant the assumption that vitamin A plays an important part in conferring resistance to many types of infection. We think that the study of the etiology of some infective conditions cannot be complete without including the consideration of this dietetic factor. We suggest, for instance, that the problem of puerperal septicaemia, and even that of acute rheumatism, might be considered in relation to the vitamin A intake. The importance of vitamin D has attracted great attention recently, and it has even been suggested that preparations of vitamin D can be safely substituted for cod-liver oil in medical treatment. The work above described shows that this teaching is erroneous, and that, although vitamin D controls, probably absolutely, the calcification of bones and teeth, it has no direct power to promote resistance to infection in the same way as vitamin A. If a substitute for cod-liver oil is given it ought to be at least as powerful as this oil in its content of both vitamins A and D.

SUMMARY

In an extensive study of animals brought up on a diet deficient in vitamin A it is shown that practically all die with some infective or progenic lesions. In the control animals receiving vitamin A these lesions are absent. The presence of vitamin D does not prevent the development of these morbid conditions, and this vitamin seems to be unrelated to resistance to infection.

The lesions produced in animals by diets deficient in vitamin A are commonly found in man, and it is desirable that this fact should be borne in mind in the study and

treatment of these and other infective and pyogenic conditions

LOW BACKACHE AND SCIATICA *

BY

W A COCHRANE, F.R.C.S.E.,

Assistant Surgeon, Royal Infirmary, Edinburgh

This paper represents an attempt to discuss the painful "low back" from the orthopaedic standpoint. It may occur with or without sciatica, and, for the sake of clearness, the writer proposes to discuss the pathogenesis of the sciatica in a separate section.

In cases of backache and sciatica a careful eliminative diagnosis leaves a large group which is essentially orthopaedic. It includes the industrial lame backs—a large and important element of industrial accident cases. In one large works back strains and injuries of this type are responsible for 20 per cent. of all accidents.

Cases of low backache and sciatica are full of interest and importance because of their frequency, of the lack of accurate diagnosis and classification, and of the difficulty in some cases of disproving the assertion of pain. We have to investigate, first, as to whether pain really exists, and second, as to the traumatic element in the lesion which is discovered. Let the writer begin by emphasizing the great importance of a routine method of examination in these cases. The physical examination of the painful back is a painstaking and meticulous performance, which cannot be learnt without study. Superficial examination will entirely fail to bring out the points on which the real scientific analysis of those cases depends. Next in importance is the necessary knowledge of anatomy and statics of the body as a whole and of the parts concerned, which can interpret the findings intelligently. The detail of the step-by-step procedure advisable in such cases has been well described by Osgood and Morrison.¹ Suffice it to say that, if completely carried out and interpreted in accordance with anatomical fact and functional use of the body, it will go far to improve upon the standard of knowledge and treatment which commonly exists to-day. The writer would submit that it has been due to the fundamental work of the Boston school of orthopaedic surgeons, and particularly to Goldthwait, that the whole subject has become clarified. This is a great and enduring achievement.

In this country we have been apt to regard this whole field as unknown—the happy hunting ground of the quack, by whatever name he may be called. Fortunately, indications are not lacking that greater interest is being taken in the subject of backache and sciatica. In this connexion the Lady Jones Lecture of 1927, delivered by Putti, upon the pathogenesis of sciatica, may be cited as an example, and a vast bibliography has grown up.

It seems to the writer that general discussion of the subject may well be centred round the following: (1) the main problems, (2) special points and methods of diagnosis, (3) a suitable clinical classification, (4) methods of treatment.

THE MAIN PROBLEMS

1 The first problem is in regard to the anatomical type of the individual concerned, for special consideration has to be paid to the slender, tall and lanky, or small and delicate type of patient. These individuals are especially unsuited to heavy work and, even under ordinary conditions of life, they are subject to functional breakdown in regard to the back. The spine is slender, hypermobile, and wand-like. There is a true, inherent weakness, and it most commonly betrays itself in general postural strain, or in symptoms of strain referred to the sacro-iliac joint.

2 The second problem concerns cases of backache, with or without sciatica, in individuals who use the body in poor posture and in positions of mechanical disadvantage. With incorrect bodily mechanics, all the antero-posterior curves of the spine are increased, and the joints are used at their extreme limit of motion. The normal balancing mechanism of the body is impaired and the load is borne by bony and ligamentous supports. The lumbo-sacral joints in particular are overloaded in heavy subjects with prominent sagging abdomens, and a chronic lumbo-sacral strain commonly results.

The other part of the "low back" which is exposed to static insult from this source is the sacro-iliac joint. The pelvis is being tilted forwards, the support of the joints becomes less efficient. The muscular support of the pelvis, which Goldthwait has shown is so important in the support of these true articulations, becomes impaired. The sacrum may be regarded as a see-saw swung on a transverse axis passing through the sacro-iliac joints. The shorter upper arm is weighted by the body, which tends to thrust it downward and forward. If the individual is bending and lifting a heavy load, and the load slips, a severe stretching of the sacro-iliac ligaments can, and does, take place. Pain is experienced over the joint, and the clinical features are quite definite. Leverage in the opposite direction through the hamstrings is also effective in straining the joint. Post-operative backache is due to a sacro-iliac strain from insufficient support of the lumbar region. The faulty statics may be due to a short leg, flat-foot, or an affection of the hip.

3 The next problem arises when x-rays reveal no intrinsic lesion of the lumbo-sacro-iliac region. As Osgood and Morrison point out, the need for accurate diagnosis in these cases is acute. Our first object should be to demonstrate the presence or absence of persisting strains. It should be stated that a negative x-ray photograph is not sufficient to warrant the assumption that there is nothing the matter with the patient. In point of fact, careful reading of good radiographs will frequently reveal a departure from the normal in many cases of extrinsic lesions. For example, ossification of the iliac attachment of the ilio-lumbar ligament is always due to lumbo-sacral strain of long duration. The more the subject is studied, the more is one impressed by the help which good stereoscopic and lateral x-ray photographs are in support of a routine and systematic examination.

4 Next is the discovery in the radiograph of an intrinsic lesion of the spine, such as osteo-arthritis, in cases of alleged injury. The symptoms are usually out of all proportion to the severity of the trauma. This furnishes the main class of case for medico-legal battles. Compression fractures of the spine sometimes follow comparatively minor violence, and represent the most commonly overlooked industrial lesion. It is remarkable how frequently a lesion of the spine is overlooked in the antero-posterior view radiograph, to be shown quite clearly in the lateral view.

5 The problem which next merits attention is the difficult and complex question of the relationship of anatomical variations of the fifth lumbar vertebra to backache and sciatica. One would refer particularly to semi sacralization, variation in the shape and direction of the articular facets, and to spina bifida occulta.

What is the connexion between these variations and backache and sciatica? Is the association casual or causal?

* Read in opening a discussion in the Section of Orthopaedics of the Annual Meeting of the British Medical Association, Cardiff, 1928.

These abnormalities have existed long before symptoms of pain in the back began. When any considerable departure from the normal exists, however, a careful history will often reveal that the patient has had periodic attacks of pain. These backs are apt to be intermittently symptomatic. As Osgood puts it, the abnormality is to be regarded as potentially contributory. These backs are more easily strained than the normal. It is unquestionable that the connection between the occurrence and persistence of symptoms and the presence of these abnormalities is an intimate one. O'Reilly's² large series of anatomic variations indicates that 50 per cent had back symptoms of varying severity. Poor posture, injury, and advancing age combine to make the abnormality manifest itself, and the chain is complete.

6 In cases of injury the most difficult problem is the mental one. Conn³ has pointed out that the traumatic back still enjoys an unenviable notoriety as a rock behind refuge for malingerers. The reputation is not always merited. Malingerers are not with, but they are not common. One factor worth remembering is that the workman is often genuinely deceived as to the true sequence of events which have led up to his disability. A second factor is that the man realizes that he has little to show for his symptoms and is apt, therefore, to exaggerate. He feels that the onus of proof rests with him.

DIAGNOSIS

The differentiation of the various types of backache is always difficult and can be made only after the elimination of definite intrinsic pathological lesions of the bones and joints—such as tuberculosis, syphilis, arthritis, osteomyelitis, neoplasm, spondylolisthesis, and fracture.

The chief points to be noted are the general build and attitude of the patient, the presence or absence of the normal lumbar curve, of list or lateral deviation of the spine, restricted and painful movements of the spine and hips in standing, sitting, and lying, spasm or wasting of the muscles, swelling and points of tenderness over the lumbosacroiliac regions, rectal examination, and the nerve function in the legs.

In addition to the ordinary x-ray photographs stereoscopic views should be taken which include the symphysis pubis. Lateral views of the spine should also always be taken.

CLINICAL CLASSIFICATION

The following may be accepted as a suitable clinical classification: (1) Acute traumatic strain, (2) General postural strain, (3) Lumbo-sacral strain, (4) Sacro iliac strain, (5) Combined pelvic joint strain.

1 Acute Traumatic Strain

This lesion represents a rupture of ligamentous and muscular fibres, with all the phenomena of acute injury. The connection between trauma and violent effort and the sudden development of symptoms is always definite. A lesion in the muscle gives rise to pain when the muscle is thrown into action, a lesion in fibrous tissue when the fibrous tissue is put upon the stretch, a lesion of bone or joint on all movements of the spine. There is acute tenderness on pressure, localized over the site of the lesion. From its location, and from analysis of the spinal movements which are most painful, a fair idea of the structures involved may be obtained. The treatment of a torn muscle must be to rest it until healing has taken place. Most of these cases in industrial back-accident cases are allowed to use the muscles too soon and with insufficient protection. If there is a superadded infective focus present in the body—whether in teeth, tonsils, or alimentary tract—there is reason to suppose that this may be a potent factor in keeping up the disability. When the disability has become chronic, it is due, in large part, to the perpetuation of the protective response of the muscles to prevent motion of the spine. Such fixation is crippling and manipulation under an anaesthetic is then advisable.

To secure the required rest the patient should be made recumbent on a firm mattress and should have the back splinted with adhesive strapping. The knees should be supported on a pillow. In severe cases, a plaster-of-Paris jacket should be employed or recumbency in a plaster shell.

The patient is then allowed up and given heat, massage, and graduated exercises. If handled properly the condition of acute traumatic strain is curable in a short period of time, and the multitude of such cases which are allowed to go about with chronic disability and incapacity for work represents in some measure, a reproach to us. Stress must again be laid upon the fundamental factor of poor bodily mechanics and posture as tending to perpetuate the disability, and the necessity for physical education to eliminate it.

While complete rest is advisable for a torn muscle or aponeurosis, a sprained joint should be made active as soon as possible, and correction of the poor general statics enforced.

2 General Postural Strain

In this case the condition is one of general muscular fatigue and ligamentous strain, and is not confined to any one joint. The complaint is of dull aching in the shoulders and low back, coming on when the patient is tired, and relieved by rest. The patients are of the slender asthenic type, and investigation may show that they are engaged in occupations which are unusually fatiguing or which favour the adoption of faulty attitudes. There is usually no referred pain in the leg. Examination shows poor posture. There is no limitation of motion in the spine or in the hips, and muscle spasm is absent. Treatment is by rest, support, and postural re-education.

3 Lumbo-sacral Strain

The pain, dull or acute, is localized in an indefinite way over the lower spine and hip, affecting chiefly one side, or in other cases being referred quite definitely to the lumbosacral angle. It is usually asymmetrical, and sciatica is a frequent symptom. This kind of backache is generally relieved by rest. One outstanding type is seen in the stout person with heavy, protruding abdomen. In order to accommodate the increased weight in front, the patient tilts the spine backwards, with the production of excessive lordosis. The body weight is taken upon the spinal arches, the impinging spinous processes (they are seen faceted in a radiogram), and upon the locked-home lumbosacral articulations. Examination shows bad posture. Spinal movements are usually fairly free but on lateral bending the participation of the lower lumbar vertebrae in the movement is often greater in one direction than the other. Forward bending is limited by spasm of the hamstring muscles, limiting the flexion of the pelvis on the hips. There is local tenderness on deep pressure in the lumbosacral region over the articulations, or further out at the attachment of the ilio-lumbar ligaments to the iliac crests. The hip motions are free, but flexion of the hip with the knee extended ("straight-leg raising") is limited on the affected side. Nerve examination may show disturbance of cutaneous sensibility and muscular atrophy in the lower limb of the same side.

The treatment is as under the previous section. The patient is made recumbent on a hard mattress with a pillow beneath the knees. He is rolled over on to the face three daily for three-quarters of an hour, and hot fomentations are applied. When the soreness has gone out of the back he is instructed in a long-down list of exercises, with a view to educating him in flattening the lumbar spine. He is allowed up in a plaster jacket or in a brace which spans the lumbar curve and helps his muscles in attaining the correct position for the spine, which they are taught to do by postural training. When he understands the elements of proper bodily mechanics, the brace is gradually discarded. In women a carefully fitted corset is worn over the brace.

4 Sacro iliac Strain

In contrast to lumbosacral strain, which usually affects the heavy type of person and is relieved by recumbency, sacro iliac strain is commonest in the slender, viscerotonic type which uses the body in poor posture. The back becomes lordotic, the ligaments gradually stretch out and, in exceptional cases, a minor displacement may take place, the upper part of the sacrum moving forward. Positive evidence of this may sometimes be discovered in the fact that the posterior superior iliac spines are on slightly different levels, also, in asymmetry at the symphysis pubis.

as seen in an x-ray photograph. The so-called subluxation of the sacro-iliac joint occurs, but it is rare. Sacro-iliac joint strain is, however, common.

In acute injuries of the healthy joint the posterior ligaments prevent forward dislocation of the upper part of the sacrum. When the body weight is bent forward and the lifting of a heavy weight is started, the back muscles contract, fixing the spine. The iliac part of the gluteus maximus and the hamstrings become taut to fix the pelvis, and the only muscle free to act is the sacral division of the gluteus maximus. This violently pulls the lower part of the sacrum forward, shearing the joint surfaces, and a true synovitis results (Lusskin*). There is present a flat back, scoliosis, tenderness over the joint, and hamstring spasm. Sometimes violent leverage is exerted upon the joint through the hamstring muscles.

The joint is supplied by the lumbo-sacral cord, the first and second sacral nerves, and the superior gluteal nerve. Referred pain is usually along the first and second sacral nerves—posterior aspect of thigh—to outer side of leg and ankle. Because of the nerve supply of the superior gluteal, pain is referred to the sacro-sciatic notch and extends antero-laterally towards the anterior iliac spine. The tender spots in traumatic or inflammatory conditions of the sacro-iliac joint are

1. The inferior sacro-iliac ligament, between the posterior and inferior iliac spines
2. Sacro sciatic notch
3. Sometimes the sciatic nerve trunk

Motions

Standing—In forward bending the lumbar spine is flexed. Then the pelvis is tilted forwards until the hamstrings are taut. At this point the patient has to flex the knee of the affected side. In lumbo-sacral conditions the lumbo-sacral region is kept rigid, and forward bending takes place at the hip-joints.

Sitting—In sitting the hamstrings are relaxed and consequently the patient can bend forward more easily. In lumbo-sacral conditions the movement is just as limited as in standing.

Lying—If both hips are flexed with the knees bent, in lumbo-sacral conditions, there is still pain and limitation of movement as soon as the pelvis begins to be flexed upon the lumbar spine. In sacro-iliac conditions no leverage is exerted and the movement is free. If, however, the limb on the affected side is raised with the knee extended, the hamstrings become taut and leverage is exerted on the sacro-iliac joint, pain is experienced over the joint. Similarly, if the same test is tried with the other limb, pain is frequently experienced over the sacro-iliac joint of the side opposite to that of the raised limb.

The description of the diagnostic points given largely follows that of Smith-Petersen,⁵ who has based his account of the clinical features upon fifty cases—thirty of strain and twenty of inflammatory conditions—confirmed by operation to produce ankylosis of the joint.

Treatment

The treatment of sacro-iliac strain is by rest and support, with heat and massage later, followed by education of the muscles to flatten the lumbar spine and to undo the abnormal forward tilting of the pelvis. Most of the mild cases are relieved by strapping, but more commonly a light brace and well-made corset are required for a time.

In the more resistant cases the joint must be manipulated under an anaesthetic. The assistant fixes the pelvis, the surgeon flexes the affected limb, with the knee extended to the right-angled position, until the hamstrings are felt to give. In still more resistant cases Smith-Petersen's operation to ankylose the joint may be required.

5 Combined Pelvic Joint Strain

Clinical features referable to both lumbo-sacral and sacro-iliac joints may be found together, this occurs sometimes in semi-sacralization of the fifth lumbar vertebra. In one specimen bony ankylosis had taken place in the accessory articulation, and in the sacro-iliac joint of the same side from arthritis. Presumably the patient must have had

severe symptoms for years—to obtain relief when ankylosis occurred. An enlarged fifth lumbar transverse process giving rise to local and referred pain usually responds to conservative treatment by prolonged immobilization and support. Removal by operation has often been practised with good effects in the resistant type of case. An alternative and a better plan is to ankylose the lumbo-sacral region by a fusion or bone-grafting operation.

A NOTE ON THE PATHOGENESIS OF IDIOPATHIC SCIATICA

A mass of reliable evidence is now available to prove that the cause of many cases of sciatica is to be traced to an anatomical abnormality or lesion in the lumbo-sacral region of the spine. The diagnostic features indicate a lesion of the joint by localized pain and tenderness on deep pressure, by asymmetrical immobility of the spine—sciatic scoliosis—and by pain referred along the sciatic nerve. Whilst the nerve itself may occasionally be tender, it is commonly not so in such cases. Goldthwait of Boston was the first to investigate the problem from the anatomical and mechanical aspects, with the result that painful semi-sacralization of the fifth lumbar vertebra is now a well-recognized entity. There is irritation of the sciatic nerve, combined with protective deviation of the spine from the vertical in a direction away from the enlarged transverse process. This deformity of the spine may simply be attitudinal and protective, as when no actual accessory articulation exists. When a very large unilateral sacralization exists it may cause a simple, fixed scoliosis without very obvious muscle-spasm. Deep seated tenderness, best elicited when the patient is kneeling, can be discovered to be present over the accessory articulation, and not over the lumbo-sacral articulations.

Discussing the mechanical factor present in referred sciatic pain in cases of unilateral enlargement of the fifth lumbar transverse process, Bauman⁶ regards the distinct forward bulge of the process as a definite factor in producing overstretching of the lumbo-sacral cord. He was impressed by this in the thirty-five cases operated upon for the relief of the sciatica by removal of the process. Almost every one of these cases was permanently successful. Many other similar cases are reported in the literature.

Putti⁷ regards many of the cases of sciatica as a neuralgia, caused by pathological conditions of the intervertebral foramina, and especially of the intervertebral articulations. The common cause is chronic arthritis.

He calls attention to that part of the nerve trunk which occupies the intervertebral foramen, the funicular portion of the nerve, lying between the spinal root and the plexus. The foramen is a fibro-osseous canal, bounded posteriorly by the articular facets. The foramen between the fifth lumbar vertebra and the sacrum is the smallest, and the size increases from below upwards in the lumbar region. Quite contrary to the size of the foramen is the size of the enclosed lumbar nerves. The fifth lumbar root is the largest, and the others diminish from below upwards. In point of fact, the fifth root completely fills up the canal and is in very close relationship to the intervertebral disc, so that displacement of the body of the fifth lumbar vertebra, as in spondylolisthesis, may easily compress this trunk. The blood vessels are especially prominent as a plexus in the foramen, so that congestion of the vessels, as in a chill or rheumatism, may affect the contained nerve.

The size of the foramen is alterable by movements of the spine. In poor posture associated with increased lumbar lordosis, the available room for the fifth and, to a lesser extent, the fourth lumbar nerve may be seriously diminished. If, in addition, there is a sudden hyper-extension injury, it is not difficult to understand that a synovitis of the joint may affect the nerve lying in front. And so with chronic arthritis of the lumbar joints. This condition can be discovered even in the early stages by good radiographs, it is not uncommon in cases of chronic lumbo-sacral strain associated with sciatica.

Abnormalities of the facets are not unusual. Instead of being crescentic, one or both of the lumbo-sacral facets may be flat, and may occupy the coronal plane. If this is associated with other abnormalities of the fifth lumbar vertebra, such as semi-sacralization, and with increased lumbar lordosis from poor posture, the room available

within the related foramen may be so seriously lessened as to set up sciatic pain.

In these cases the maximum tenderness is over the affected articulation, and protective sciatic scoliosis is usually present. Treatment must be by prolonged recumbency and immobilization of the spine, if necessary in a plaster shell, combined with hyperaemia. In the convalescent stage a supportive brace must be worn and postural re-education begun. In one resistant case Putti resected the diseased posterior articulations, with good effects.

CONCLUSIONS

Cases of low backache and sciatica form a distinct orthopaedic group. They are capable of definite scientific analysis and classification.

To study them intelligently requires an appreciation of certain main problems which are indicated. The factors of trauma, anatomical type, good and bad posture, of anatomical variations, and of pathological lesions of the spine are all concerned in what is really a combination problem.

To make our diagnosis more accurate a routine and systematic method of physical examination is required.

Skilled interpretation of good x-ray photographs, by those familiar with the clinical picture, is the most valuable accessory aid in support of the diagnosis made by the history and examination.

PERFORATED DUODENAL ULCER SIMULATING ACUTE APPENDICITIS

BY

K C L PADDLE, M C, M R C S, L R C P, D P M,

SENIOR ASSISTANT MEDICAL OFFICER WEST RIDING MENTAL HOSPITAL
WAKEFIELD

Cases of perforated duodenal ulcer simulating appendicitis in normal people are, I believe, comparatively common. The symptoms presented in such cases are usually so urgent that there is no difficulty in making a diagnosis. Those who have seen the acute abdomen in the insane, however, will no doubt agree that there is a real difficulty in making up our minds that there is anything urgent and requiring immediate attention. Yet, if a waiting policy is adopted, the consequences are usually disastrous. The following case presents unusual features of interest.

The patient a man aged 36 was admitted to this institution on October 26th 1921, suffering from dementia praecox. He was dull and sullen never speaking voluntarily or taking any interest in his surroundings whatever. He was quite unemployable and was occasionally impulsive and destructive. He suffered from an intractable form of impetigo but was otherwise in quite good bodily health.

On May 13th last he vomited once just before being put to bed at 10 p.m. His temperature, pulse, and respirations were normal at the time and he did not complain of pain and looked quite well. He got up next morning at 7.30 apparently quite well had breakfast at 8 and vomited soon after. His pulse, temperature and respirations were normal. He was however put to bed for safety though he looked well and did not complain. At 1 p.m. five hours later his pulse rate had risen to 102 and his temperature to 101° F. He then looked ill. He lay absolutely still on his back with his right leg slightly drawn up. His tongue was dry and furred, respirations about 22, but his abdomen moved fairly well rhythmically. On examination there was some rigidity of the abdominal muscles on both sides but nothing marked. There was no superficial tenderness but the patient resented deep palpation of the right iliac fossa though he did not seem to mind deep palpation of the left side. The heart and lungs were normal the urine also was normal. He would not reply to questions as to his condition and gave little help. He however undoubtedly suffered from an acute abdomen a provisional diagnosis of acute appendicitis was made and the patient was hurried to the operating theatre.

Operation.—A right paramedian incision was made the right rectus being drawn inwards. The peritoneum was incised and was found to be acutely inflamed. A lot of dirty looking non purulent

fluid exuded. After careful separation of recent adhesions between coils of small intestine the appendix was isolated and, except for the general peritonitis present was found to be quite normal. It was removed. The original incision was next prolonged upwards for about two inches and the right side of the abdomen explored. A lot of the turbid fluid was tracking downwards and on exposing the duodenum (second part) a fairly large perforation was found with prolapsed mucous membrane showing. There was little induration round the perforation which admitted the tip of the middle finger easily. It seemed to be of the nature of an acute duodenal ulcer. A purse-string suture was inserted round the perforation and the ulcer buried. The right side of the abdomen was next irrigated with warm normal saline and drainage tubes were placed in the lower part of the wound to drain the pelvis and also tubes were inserted in the right lumbar region through an incision in the right flank.

The patient made an excellent recovery. Ten days later however he commenced vomiting during the night and right up till noon next day when the vomited matter became faecal. All food was stopped and the patient only allowed to drink the following:

R Sod bicarb	1 part
Mag carb pond	2 parts
Calc carb	2
Bismuth oxyearb	4
Water q.s. to a cream consistency	
Sig. 3i in 3iv water every two hours	

Vomiting ceased two hours after taking the first dose, and from that time onwards the patient made an uninterrupted recovery his abdominal wound healing up by granulation.

The points to remember in this case are

- 1 The perforation took place at least some eighteen hours before operation, probably soon before 10 o'clock the night previously, when he vomited for the first time.
- 2 There were no constitutional disturbances until after breakfast next morning at 8 o'clock, and then only very little after that.
- 3 The great difficulty in diagnosis owing to the patient's mental condition and lack of positive symptoms.
- 4 The threshold for pain in this case was very much lowered.
- 5 The importance of eliminating acute disease in the patient's other systems, such as respiratory, vascular, and urinary.
- 6 The usefulness of an alkaline bismuth mixture in relieving high intestinal obstruction, due to oedema of mucous membrane at the site of an ulcer.

I am greatly indebted to the medical director Professor J Shaw Bolton for his able guidance during the operation and for kind permission to publish details of this case.

Memoranda :

MEDICAL, SURGICAL, OBSTETRICAL.

A PLASTIC PROCEDURE IN THE MASTOID OPERATION

SEVERAL methods are in vogue for obtaining an epithelial flap or flaps in the radical and conservative mastoid operations which, although in practice they appear sound on theoretical grounds, are not infrequently disappointing. In both these operations I have employed the following simple procedure with gratifying results.

The posterior cartilaginous wall of the meatus is separated from the corresponding bony portion and the cartilage is transected by a flap knife or tonotome at the upper end of the junction between the external auditory meatus and the concha, and divided vertically along this line through a length corresponding to the vertical diameter of the meatus. From the upper end of this incision another is carried inwards at right angles through the whole width of the cartilaginous meatus a rectangular flap being thereby obtained with its base attached to the inferior wall of the cartilaginous meatus. The cartilage included in the flap is excised.

The flap is now held aside by tissue-forceps until the bone-work of the operation is completed. This done a small crescent is excised from the inner cut edge of the concha to produce a large meatal orifice. The flap is next turned down on the lower wall of the operation cavity and its outer edge sutured to the skin edge of the lower part of the inner semicircular conchal margin sufficient of this having been removed by the crescentic excision to make room for the edge of the flap without kinking it. The deeper part of the flap is maintained in position by wool or gauze packing until it has become united by granulation tissue to the inner wall of the operation cavity, when this occurs packing may be dispensed with. The discharge is gently mopped away and the walls of the cavity are treated twice daily with a stimulating lotion such as lotio rubra. Hydrogen peroxide should not be used since it tends to undermine the flap.

This simple procedure may be quickly performed, and it has the following advantages

- 1 Cutting the flap at an early stage permits of an excellent view of the "operative field" throughout the operation
- 2 The large external auditory meatus gives easy access to the operation cavity for purposes of examination and dressing
- 3 A useful area of cavity is immediately epithelialized, and granulation tissue is prevented from growing in excess over an area where this frequently occurs
- 4 The position of the flap directs the growth of new epithelium around the walls of the cavity
- 5 There is no tension on the flap and no difficulty in maintaining it in position owing to the excision of its cartilage
- 6 The method hastens healing considerably

FOREIGN BODIES IN THE ALIMENTARY TRACT

The following case is of interest owing to the character and variety of the articles swallowed

A boy, aged 14 was admitted to Greenock Royal Infirmary in 1927 with a history of having swallowed something two hours previously. On inquiry the information was elicited that, while in a house of detention pending his removal to a reformatory the boy had broken two safety pins at their joints bent the pieces double, and swallowed them. In addition he had swallowed an ordinary safety pin (closed). These were followed by a large collar stud, two trousers buttons and several small pieces of coke.

Examination revealed him to be a healthy boy, well developed physically, though perhaps a little under the average intelligence for boys of his age. The pulse rate on admission was under 80, and the temperature 98° F., he seemed fairly comfortable, although he complained of some abdominal pain. Palpation revealed definite tenderness all over the epigastrium, most severe slightly to the right of the mid line. On x-ray examination all the articles were seen in

the stomach near the pylorus but it was found that the sharp pointed half of one of the tiepins had been swallowed without being bent double.

After the first few hours in hospital the pain subsided and the boy was watched most carefully, he was kept on a diet of soft foods and the abdomen was screened daily. On the tenth day the first article (a trousers button) was passed and the others followed at the rate of about one each day. Four days in succession the fluorescent screen showed the unbent half tiepin in the mid line at the level of the umbilicus, where it had apparently stuck but it was eventually passed on the seventeenth day without untoward symptoms developing. No purgative medicine was given until two days after the last article had been passed.

The x-ray reproduction shows the articles well down the gut, and the sharp half tiepin is seen very faintly at the top of it.

I am indebted to Dr W A Milne, honorary surgeon to the infirmary, under whose care the boy was admitted, for permission to use these notes.

CHARLES GILMOUR, M.B., Ch.B.
Late House-Surgeon, Greenock Royal Infirmary

TRAUMATIC RUPTURE OF THE SPLEEN

RECOVERY after splenectomy in instances of traumatic rupture of the spleen has been so frequently recorded in the journals that it becomes almost commonplace, and in describing the two cases which follow it is to their unusual clinical histories before operation that I would draw particular attention.

A labourer aged 36 was admitted to the Swansea General Hospital on April 28th. He gave a history of having been awakened during the night by acute abdominal pain accompanied by vomiting and a severe attack of shivering. His doctor was not

called until the following morning, and he immediately sent the patient to hospital having diagnosed a perforated duodenal ulcer. On examination the abdomen was found to be generally rigid although more particularly over the lower portion of the right rectus muscle than elsewhere. Signs of free fluid were readily elicited in both flanks, and the patient was obviously ill, although a temperature of 102° F., a pulse of 110, and respirations of 24 did not indicate a collapsed condition. A tentative diagnosis of appendix peritonitis was made, and I opened the abdomen by a right pararectal incision. A large quantity of free blood escaped on incising the peritoneum an occurrence which was decidedly bewildering. The incision was enlarged and the first discovery of pathological importance was that of numerous caseating tuberculous glands in the mesentery. Finally, after a diligent search, a large tear was discovered on the convex surface of the spleen, which was considerably enlarged and friable. In order to perform splenectomy it was necessary to sever the right rectus muscle, high up, and to turn back a flap of the abdominal wall. Following operation the patient developed pneumonia, and his wound gave way in its upper half, he recovered well, however, and healed rapidly after secondary suture. He was discharged on June 11th, and remains well. It was only during the week following operation that the probable cause of the lesion was discovered. On the evening before admission the patient, while intoxicated, had lurched and fallen against the stair rail, he had gone to bed and to sleep immediately, and had no recollection of his accident when he was awakened by the pain. It must be admitted that the severity of the injury sustained would be insufficient to rupture a healthy person's spleen, but in the case of an organ twice the normal size and rendered friable by the associated abdominal tuberculosis the history of trauma is a more acceptable explanation of the cause of the tear than would be that of a spontaneous splenic rupture.

A collier, aged 50, was admitted on June 18th. He gave a history of having been crushed between two trucks a few hours previously, and had obviously fractured three lower ribs on the right side. There was some generalized abdominal tenderness, but no rigidity. The temperature was 98° F. the pulse 80 and the respirations 32. Progress was so satisfactory during the four days immediately following admission that discharge from hospital was contemplated. At 2.30 a.m. however on June 23rd the patient suddenly collapsed during defaecation and a diagnosis of brisk internal haemorrhage was readily arrived at. On this occasion I made a left paramedian incision, and blood was found to be pouring from the hilum of the spleen in the neighbourhood of which there was an extensive tear. Splenectomy was performed, and on examining the organ subsequently its capsule was found to be almost entirely stripped off and very lax. Evidently in this instance the primary lesion was an intracapsular rupture, haemorrhage being arrested in all probability by the resistance which was offered by the distended capsule. On June 23rd the rise in blood pressure caused by straining at stool must have been sufficient to recommence the haemorrhage, with rupture of the capsule and occurrence of free intra-abdominal bleeding. After a critical illness lasting for a few days the patient recovered rapidly, his wound healed by first intention, and he was discharged on July 12th.

VARICELLA FOLLOWED BY HERPES

A REPORT of a case of herpes zoster following varicella in the same individual may be worthy of publication, in view of the fact that, according to recent correspondence in the *British Medical Journal*, this sequence is apparently unique.

A well-grown and healthy boy, aged 12, contracted chicken pox during an epidemic in York on June 28th with the usual very slight fever and a few vesicles on the chest. Two days later the chicken pox rash had completed its appearance and was generalized in the form of a profuse discrete normal varicella. The temperature was then normal. On that day he complained of fairly severe pain in the region of the left knee and down the inner side of the left leg which was tender. The pain was sufficiently severe to make the possibility of osteomyelitis pass through my mind but there was no rise of temperature.

On the fourth day from the commencement of a typical herpes rash appeared in two patches one on the inner side of the thigh just above the knee and the other half way down the inner side of the leg. The herpetic rash was quite typical in its even and close distribution, and contrasted with the discrete and varied varicella rash, which by then was almost completely scabbed over.

I refrained from publishing the case (as I had originally intended) in view of the appearance of the contribution from Dr Grny Hill, published on August 4th (p 197), from which it was plain that cases of varicella and herpes in the same person were not uncommon.

However, in view of the letter from Dr W P Le Feuvre, appearing on September 22nd (p 549), in which it is categorically stated that no case of herpes zoster appearing in the same individual in relation to varicella, but subsequent to the latter, has so far been recorded, this case is apparently unique.

Incidentally, during the same epidemic (which was an unusually widespread one) the following two cases of relation between herpes and varicella in different individuals came under my notice

A boy attending the same school as the previous patient was sent home with shingles a week later his sister developed chicken pox

Of two boys both aged 5 who were playmates living next door to each other one developed chicken pox and a week later the other developed shingles in one patch below the left axilla at the level of the nipple

Thus to the 176 cases of relationship recorded in the *British Medical Journal* in the past fourteen or fifteen years I am able to add three occurring within a few weeks of each other in quite a small area

YORK. J. C. LYTH, M.B., B.S. Lond

TORSION OF GREAT OMENTUM

The following case seems of sufficient interest to be placed on record

The patient a 4-paras aged 40 was admitted to hospital with acute abdominal symptoms. Some six months previously she had had an attack of acute abdominal pain accompanied by vomiting and severe headache. The pain settled down somewhat and was most marked in the left side. She remained in bed for four to five weeks. After getting up she never felt well constipation was a marked feature. Two days before admission there was a recurrence of the same pain the attack was more severe than before and was accompanied by vomiting and diarrhoea.

On admission the temperature was 100.5° F. and the pulse 160 there was great tenderness and rigidity over the left rectus muscle, and the patient complained repeatedly during the examination. There was no disturbance of menstruation but the patient stated she had felt hotter during her menstrual periods. Examination of the right iliac fossa revealed nothing abnormal deep palpation being permitted without complaint the patient would not admit the pain ever settling down over McBurney's point.

The abdomen was opened by a left paramedian incision and a large mass was found in the left paracolic gutter surrounded by a few adhesions. When freed it was found to be the great omentum which had undergone torsion at the lower border of the transverse colon the mass was acutely inflamed and gangrenous was threatening. It was transfixed and ligatured at the lower border of the transverse colon where a distinct fibrous band could be seen encircling the constricted neck. The abdomen was closed and a drainage tube which had been inserted was removed three days later the patient made a good recovery. The weight of the portion removed was 15 oz.

I am indebted to Mr R. W. Thompson visiting surgeon Walsall General Hospital for permission to publish this case.

Reports of Societies.

PERINEAL PROSTATECTOMY

A SPECIAL meeting of the Section of Urology was held at the Royal Society of Medicine on October 4th, when Dr O. S. LOWSLEY of New York opened a discussion on perineal prostatectomy. Lord Dawson of Penn., President of the Society who was in the chair and introduced Dr Lowsley, said that such a relationship as existed between medical practitioners of different nationalities and especially between those of either side of the Atlantic, should exist between nations as a whole. As a physician he saw only the bad results from such operations as prostatectomy, and for that reason he would be glad to have mitigated his unfavourable impressions associated with that operation.

Dr LOWSLEY said that the only difference between a good urological surgeon and a good general surgeon was that the former possessed certain instruments of precision not owned by the latter, he would therefore demonstrate some special instruments he had found useful, including a modification of Mr Kidd's cystoscope for fulgurating large bladder growths, a rongeur, a posterior urethroscope for heating up the prostate by means of diathermy in cases of prostatitis, and a catheterizing cystoscope for infants. Dr Lowsley then dealt with the embryology of the prostate gland, and traced the various changes occurring in it from infancy to old age. By means of lantern slides he showed how the tubules of the anterior lobe atrophied at an early date, and how the glands of the posterior lobe, which were active during the height of sexual life, became shrunken

as old age approached. It was an interesting fact that carcinoma, according to J. T. Geraghty and M. L. Boyd, invariably started in this lobe, although it was never involved in any adenomatous changes. Of special interest in connection with the pathology of prostatic enlargement were the submucous glands, particularly the subcervical group first described by Alberran. Turning from the pathology to the surgery of the prostate, Dr Lowsley emphasized the importance of preliminary drainage. He himself employed drainage in all cases, whatever the state of the kidneys or the amount of residual urine might be. He preferred suprapubic drainage to that afforded by a catheter. On general principles it was a bad thing to leave a foreign body like a catheter in a urethra that was already the seat of inflammation. With suprapubic drainage the subsidence of the oedema of the prostate was more rapid and more satisfactory. In his opinion the advance that had been made in prostatic surgery of most importance next to the recognition of the necessity for preliminary drainage had been the use of local or regional anaesthesia. General anaesthetics should be avoided because they elevated the blood pressure, and this increased the haemorrhage during the operation. Moreover, as soon as the patient recovered consciousness he suffered considerable pain. By the administration of sacral and paracervical anaesthesia both these disadvantages could be avoided. So far as Dr Lowsley could estimate, there was under sacral anaesthesia only about one-tenth of the amount of bleeding which occurred with general anaesthetics. The fact that the effect of the novocain lasted for a period of six or eight hours subsequent to injection eliminated shock and pain. The third advantage was that the patient could imbibe water immediately, and did not go through the process of dehydration suffered by those taking general anaesthetics. The technique of sacral and paracervical anaesthesia was then shown by means of a cinematograph film. Dr Lowsley proceeded to describe the operation of perineal prostatectomy, which in its main line followed that of Hugh Young. The modifications employed by the speaker were the use of a special tractor devised by Crowell and the opening of the prostate by means of an inverted 'V' incision, which avoided damaging the ejaculatory ducts. Unlike Young's tractor, that of Crowell could be passed through the whole urethra into the bladder, thus avoiding the risk of damaging the external sphincter. The index finger of the left hand was inserted into the rectum in order to guard against injury during the action of dissecting away the prostate from that structure. The speaker added that in enucleating the gland an effort should be made to retain intact the internal sphincter. Any roughness in enucleation was likely to split this sphincter and to tear into the plexus Santorini. Thoroughness in removing shreds of torn tissue must be observed in the case of perineal as of suprapubic prostatectomy. Dr Lowsley paid a tribute to the English school of urology for having emphasized the importance of this point. Half-destroyed tissues became necrosed and were a future menace to the free passage of urine and also a fertile source of sepsis. After enucleation the finger was introduced into the bladder in order to make certain that no obstructive nodules remained behind in the region of Alberran's gland. Haemorrhage could be dealt with by ligature and packing, and drainage was provided by means of a rubber catheter passed through the urethra. Finally the floor of the pelvis was closed by drawing the two sides of the levator ani muscles together with a catgut suture, and the skin was sutured in the usual manner. The various steps of the operation were illustrated by means of cinematograph films, and statistical tables were shown contrasting the results obtained from the use of general and of regional anaesthesia.

Mr FRANK KING, President of the Section, said that in Great Britain it was probably admitted that the operation of suprapubic prostatectomy was slightly more dangerous than that of perineal prostatectomy. However, the perineal route presented some difficulties, and it was, perhaps, better that surgeons in general should stick to the suprapubic route rather than run the risk of the complications which might follow an unsuccessful perineal operation.

CARDIAC STIMULANTS

At a meeting of the Section of Therapeutics and Pharmacology of the Royal Society of Medicine on October 8th, Professor J. A. GUNN delivered his presidential address, taking for his subject "Cardiac stimulants."

Professor Gunn said that in addition to discrepancies between the clinical and pharmacological evidence as regards the cardiac stimulants there was little agreement among clinicians themselves and still less between pharmacologists. In spite of the researches on the circulation in recent years there was scarcely any consensus of opinion as to the therapeutic value of the drugs of this group. In discussing the reasons for this confusion some of the factors concerning the mechanism of the circulation must be recalled. The circulation of the blood was essentially a distributory scheme designed to supply the various organs of the body with blood according to the separate and varying demands of each. The efficiency of the circulation, from the point of view of the organ, was determined by the rate of blood flow within it, this depending on the pressure of the blood and the calibre of the vessels. The general supply was dependent chiefly upon the output of the heart and the calibre and elasticity of the vessels. The collecting side was equally important, because, if the uniformity of the circulation was to be maintained, exactly as much blood must be returned to the heart as had been pumped out in a given time. It was necessary to realize the vital importance of the capillary circulation, it was for this that the whole circulatory scheme was designed, but, broadly speaking, physiological research had always proceeded in the other direction—that is to say, from the consideration first of the "wholesale distribution," to the "retail delivery" and the "returned empty" traffic as secondary. The first question with regard to cardiac stimulants was whether the physician and the pharmacologist had come into line with the advances in the knowledge of the circulation, the answer must be "Not yet." Confronted with any failure of the circulation, there was still too much tendency to throw the blame on the "wholesale delivery" and to speak of "cardiac failure" when in fact the heart had nothing to do with the failure of the circulation. A good deal of the present confusion was due to want of proper classification, in the absence of which no progress could be made. Cardiac failure, for example, might occur early in chloroform administration from ventricular fibrillation, or, late, from paralysis of the heart muscle combined with central vasomotor and respiratory paralysis. In the first kind of cardiac failure, adrenaline, if it could be brought to the heart, would do more harm than good, in the second kind of failure it might save life. The same cardiac stimulant might at one time be an advantage and at another time be detrimental. Much confusion which prevailed on this subject was due to the fact that there was not a sufficiently accurate classification either of cardiac failure or of cardiac stimulants, and this want of classification seriously handicapped further advance. Before such classification could be undertaken it was necessary to define with equal accuracy the term "cardiac stimulant." Professor Gunn then discussed in turn some of the drugs which had been or were regarded as cardiac stimulants, leaving on one side certain others—for example, digitalis—as to which opinions were more definite. Strychnine in some circumstances increased the excitability of the central nervous mechanism and specifically of the vasomotor and respiratory centres, it was generally agreed that it had no direct action on heart muscle. Clinically it had been largely used in conditions in which failure of the circulation with weakness of the heart was one of the features. The point of dispute was as to how it acted. The speaker did not believe that, in respect of any action on heart muscle, strychnine had ever saved or lengthened a life. It was a central vasomotor and respiratory stimulant. Three points with regard to its therapeutic value were not sufficiently recognized. So far as the circulation was concerned, it would seem useless to employ it unless the primary failure was vascular and not cardiac, therefore, precision in diagnosis was necessary to define those cases

in which its action was likely to be useful. In the second place, assuming that vascular and not primary cardiac paresis was diagnosed, there were other points which would modify the action of strychnine. In the reaction of the nervous system, for example, the effect of stimulation depended upon the excitability of the system at the time. If the vasomotor centre was depressed by toxins strychnine might have little or no action. Finally, there was the important question of dosage. In his own clinical experience he had seen effects from strychnine only when it was given in doses of one-tenth to one-eighth of a grain. With regard to alcohol, the antagonistic views obtaining were due to the fact that alcohol was administered in two different ways, and its action differed according to the method of administration. Concentrated alcohol in the form of whisky or brandy in small amounts had been given, for example, in cases of fainting occurring in more or less healthy people. The speaker agreed with the traditional and popular view that this brought about some improvement in the circulation. The effects appeared too soon after administration to allow them to be ascribed to any action following upon absorption, they were reflex. It should be remembered that even if brandy produced no marked reflex effect on the healthy conscious person it did not follow that it would not affect a patient semi-conscious or unconscious owing to some failure of circulation, although brandy might produce a reflex effect on the medullary centres in such a case, it did not follow that it would produce the same effect in a patient suffering from gradual circulatory failure occurring in the course of a long illness. After its absorption alcohol caused some redistribution of the circulation, of this there could be no doubt in view of the flushing which followed. Alcohol altered the distribution of the blood in the direction of increasing the blood flow through the skin at the expense of the internal organs, as to when, if ever, an action of this kind benefited the patient generally it was difficult to say. Camphor, again, had been widely used as a stimulant in cases of circulatory failure, and the most divergent results had been obtained. No decisive proof had been forthcoming of any direct action on the cardiac muscle. As in the case of alcohol, more had been claimed for camphor than simply the reflex effect on the medullary centres, and it was reputed to have some beneficial effect on the circulation after absorption. Both alcohol and camphor brought about some redistribution of the blood, and it was to this, not to any cardiac action, that the improvement in the circulation was due. In the case of adrenaline, however, agreement was fairly general, everyone knew the kind of action which was being employed. In normal blood pressure the effect of adrenaline was transient, in conditions of low blood pressure and feeble heart beat adrenaline might produce a lasting improvement in the circulation. The transient nature of its action in some cases, therefore, was no valid objection. Another point was that its action was independent of the condition of the central nervous system at the time. On the other hand, adrenaline was a two-edged weapon, and the tendency had been rather to restrict its use to foiled hopes. With increasing familiarity with its action and dosage, perhaps the clinical use of it in acute cardiac failure would increase, especially in the direction of employing repeated small intravenous injections rather than one single dose. The action of pituitrin on the circulation was relatively small. It did not discriminate between the splanchnic and other vessels in the way that adrenaline did, and therefore did not cause the same redistribution of blood. It had no action on the heart, and was of no value in circulatory failure primarily due to heart failure.

Dr. KINGSLEY BARTON said that he had always been a "non-alcohol doctor," but he had found that in acute conditions a stiff dose of brandy caused a collapsed patient to revive and recover in the most extraordinary way. Alcohol was given with the idea that it would stimulate the heart, but he doubted whether it had any effect on the heart at all, if it could get into the circulation to stimulate the central nervous system, all the effects of what might be called a cardiac stimulant were forthcoming, although there was still no direct action on the heart.

Dr G A SUTHERLAND declared himself convinced that there was no such thing as a cardiac stimulant, and he believed Professor Gunn to be of the same opinion as a result of his experience. The term "cardiac stimulant" had been in use for a good many years, but it was an absolute misnomer. The profession called for a cardiac stimulant that should be applicable to all cases, but what stimulant was going to do good in the case of a heart with a beat of 180 to 200 to the minute? It was not then a question of stimulating, but of procuring rest for the heart.

Dr JOHN PARKINSON referred to the need for subdividing ordinary circulatory failures according to their clinical character. Everyone was familiar with the ordinary cardiac failure accompanying auricular fibrillation, the cardiac failure without such fibrillation, failure with flutter, and failure with paroxysmal tachycardia. The whole subject would be simplified when it became known why and how patients were affected by sudden circulatory failure, but there was a very special difficulty in applying remedies in such conditions and assessing the worth of them, in view of nature's care of the heart. The heart could stop for quite a long period, and yet recommence, it could begin to beat at a very high rate, and again recover. In discussing the value of strychnine, alcohol, camphor, and other remedies, the fact must not be forgotten that nature was capable of doing all that was asked of these drugs.

Professor E B VERNER spoke of the necessity of defining accurately what was meant by the term "cardio-muscular stimulant," and referred to the work of the late Professor E H Starling as throwing a flood of light on the whole subject. The definition of the term "cardio-muscular stimulant" could be brought down to the terms of muscular efficiency—that is to say, the relation between the amount of energy actually expended in mechanical work and the total energy changes of the heart measured by oxygen consumption. He thought it fairly certain that adrenaline could be correctly described as a cardiac stimulant. A heart driven at a constant rate by faradic stimulation would contract under the influence of adrenaline.

Dr T IZED BENNETT said that startling effects from large doses of camphor given intramuscularly were by no means rare. The camphor had very likely a peripheral effect, though he could not believe that it was merely a peripheral irritant. At the Middlesex Hospital they were accustomed not infrequently to use camphor up to 20 or 30 grains in a single administration. With regard to strychnine and alcohol, his own experience had never caused him to deviate from the accepted teaching of the pharmacologists that the effects of these two drugs were rather in opposite directions—that is to say, almost all the effects of alcohol were in the nature of depressant effects, whereas those of strychnine were largely stimulating.

HEAD INJURIES

At a meeting of the Section of Neurology of the Royal Society of Medicine on October 11th, Mr DONALD ARMOUR delivered the presidential address, and took for his subject "Some considerations on head injuries."

Mr Armour said that John Bell, writing a century and a quarter ago, had expressed what would be his main thesis: "And we have this encouragement to consider the pathology in place of the anatomy of the skull as the rule of our prognostics, that while anatomy and the enumeration and classification of fractures has led to an undue propensity to operation, the study of the living powers, and the mutual dependence of these parts, leads to a reserved, modest, and rational practice, to a just confidence in the powers of nature, to a careful and solicitous attention to all the insidious symptoms of an injured brain." The speaker remarked that in the past and up to the present the subject of head injuries in the textbooks on surgery appeared in the section on "fractures" thus the mind of the medical practitioner had been imbued early with an exaggerated importance of the "enumeration and classification" of fractures of the skull, to the detriment of a proper appreciation of the much more important part of the subject—namely, the functional or

organic damage that the skull contents might have suffered. This was constantly revealed by the early insistence upon an x-ray picture of the skull being taken, following a head injury, as if the presence or not of a fracture of the skull were the important factor in the case, and as if the result of the x-ray picture would be sufficient to determine by what means and methods the associated cerebral injury should be treated. Moreover, its very use constituted at times a pitfall in forming a prognosis of a head injury, because of the false importance attached to the presence or absence of a fracture of the skull, its absence always presuming a better prognosis than its presence. For the same reason there was, he thought, a widespread lack of appreciation of the importance of so-called minor head injuries—"minor," perhaps, in the estimation of the patient and his doctor at the time, but so often "major" in their later manifestations and sequels. A general increase in intracranial pressure was the commonest result of severe head injury, this was brought about, in the first instance, by reactionary oedema or haemorrhage, or both. This increased pressure might be aggravated later or maintained by interference with the paths of absorption of the cerebro-spinal fluid, the mechanical result of the swelling or displacement of the brain itself. Such swelling or displacement interfered first by blocking the cerebral subarachnoid spaces, and, consequently, cerebro-spinal fluid collected in the basal cisterns and in the ventricles. The enlargement of the basal cisterns forced the mid-brain up, occluding the narrow spaces of the incisura tentorii. The swollen brain with its distended ventricles, pushed up against the resistant tissue, interfered still more with absorption, and so a vicious circle was established. Such was the result at any rate of a severe injury. Could the same factors in lesser degree explain the symptoms associated with or following upon a so-called minor injury? There could be no doubt that the symptoms usually following concussion—the commonest of which was headache of varying degree—were the expression of an altered pressure of the cerebro-spinal fluid. The increase of tension following upon slight injuries and maintained over a considerable period might be due to such factors—acting alone or in combination—as the increase in the amount of the cerebro-spinal fluid secreted, interference with its circulation and absorption, and variation in the volume of the cranial contents—nervous, ventricular, and vascular. With regard to the presence or absence of blood in the cerebro-spinal fluid following head injuries, the importance of this was often stressed beyond its true clinical significance. Its presence was only of significance as a corroborative sign of intracranial injury, associated with bleeding from an intradural vessel. Its absence, however, did not exclude intracranial haemorrhage, even if it was subdural or subarachnoidal. From the point of view of treatment, neither the presence nor the absence of blood in the cerebro-spinal fluid had any importance whatever. The pressure of the fluid as an indication of the degree of intracranial tension was the all-important matter.

After an interesting discussion of the eyes in head injuries, and the value of the examination of the discs in cases of local compression, Mr Armour went on to plead for the more frequent use of lumbar puncture as a therapeutic measure in both acute and chronic head injuries. While in no way a substitute for a decompression operation in cases of high intracranial tension, and being even dangerous in some cases owing to the risk of medullary compression at the foramen magnum, yet in milder cases of increased tension the slow withdrawal of fluid, repeated if necessary, was of very great value. It frequently allowed an operation to be postponed until all conditions were suitable. But the pressure of the fluid, not the quantity withdrawn, was the determining factor as to the future conduct of the case. Again, in cases obviously not requiring the major operation of decompression, but in which severe headache, extreme restlessness, irritability, and fatigue were present, repeated lumbar puncture was of the greatest value in mitigating or curing these distressing symptoms. Therein lay the value of the so-called "spontaneous decompression" in fractures of the skull with leakage of cerebro-spinal fluid—a value, unfortunately, too often offset by the ever-present danger of infection.

ALCOHOL AND DRUG ADDICTION IN RELATION TO MENTAL DISORDER

In opening a discussion of this subject at a meeting of the Society for the Study of Inebriety, in the rooms of the Medical Society of London on October 9th, Dr HUBERT J. NORMAN said the relationship was not always clear, hence there was still likely to be theorizing as to the part played by alcohol and drugs in producing mental disorder. Even so, there was a good deal which was non-contentious. Was their influence invariably deleterious? The effect upon the nervous system was only one aspect of the subject, other parts of the economy were also involved. The differential symptoms were not dealt with, but rather the common results. There was a general resemblance in the fundamental characters of the symptoms produced by these substances acting on the cerebral cortex. The differences depended more upon the quantity taken and duration of habit. The chief reason for their absorption was in order to produce euphoria and to overcome the feeling of inadequacy. The effect was to interfere with the inhibitions for which the cortex was responsible, this resulted in changes of conduct by the liberation of impulses—for example, irritability, maniacal fury, "berserk" rage, etc. These were due to the action of other areas of cells from which the inhibitions had been removed. Intellectual deterioration varying in degree followed confusion, delirium, disorientation. Association of ideas was at first stimulated, but later slowed. Imagination was increased, but the intellectual content decreased. There was impairment of the "moral sense." Illusions and hallucinations of the senses occurred and delusions were formulated, memory was also impaired—the addict suffering from amnesia and paramnesia, together with aboulia or loss of will-power, indifference, and apathy, there were periods of lucidity, but more often lack of insight.

The more common symptom-complexes were those associated with alcohol: the polyneuritic psychosis, delirium tremens, dipsomania, alcoholic paranoia, and hallucinosis. Some of these were related to the ordinary mind, possibly, non-toxic psychoses. At times the taking of alcohol was only incidental, as in association with manic-depressive insanity, general paralysis of the insane, epilepsy, and dementia praecox. Long continuance of habit, linked as it was with neuropathic defect, tended to bring the individual to the common termination of all chronic mental disorders—namely, mental impairment. The minor degrees of this might be overlooked. The nervous system had great potentiality for recovery, even after long periods of excess, it was, however, sometimes difficult to subject the patient to treatment—he had a perfect right to dope himself stupid. If, of course, cell disintegration had taken place, the patient remained to that extent mentally crippled.

Dr NORMAN quoted some examples of prominent persons who had exhibited deterioration with the taking of drink or drugs, among others he mentioned James Thomson, Poe, Richard Poison, Verlaine, Francis Thompson, Oscar Wilde, and Swinburne. The importance of the influence of excess on those who occupied positions of power was great. This had been frequently exemplified in history—for example, in the case of Judge Jeffreys.

Mental disorder in association with drugs and drink might demonstrate very clearly the difficulty in deciding between sanity and insanity, responsibility and irresponsibility, certifiability and non-certifiability. It was difficult, too, to suggest a solution of the problem of prevention. As so many of the individuals were neuropathic they were fated to become victims to some form of mental disorder. If they were prohibited from getting one substance they would obtain another.

DEGREES OF DRUNKENNESS

A MEETING of the Clinical Society of Bath was held on October 5th at the Royal United Hospital, Bath, when the chair was taken by Mr A. DE V. BLATTWART, and Dr E. SCOTT WHITE read a paper entitled "Drunk and driving a motor car."

Dr E. SCOTT WHITE suggested that a lesser degree of intoxication than usual had to be proved in order to find a

man guilty of "drunkenness" under the Criminal Justice Act. He suggested as an acid test of this state that the examiner would be unwilling to trust himself to be driven by the person accused. He gave details of some suggestions as to tests which might be applied in helping the examiner to come to a conclusion. He called particular attention to the recent work of Professor Mellanby, showing how his investigations with reference to the concentration of alcohol in the urine could be used in diagnosing various degrees of inebriety.

Clinical Cases

Dr VINCENT COATES showed a case of myositis ossificans of several years' duration in a young male adult. There were deposits in many muscles, especially the glutei and psoas, and the case was complicated by a general arthritis and spondylitis. This, together with comparative smallness of the giant toes, seemed to bring the case into the rare category of "myositis ossificans para-arthritis," described by the Polish observer Imow. Dr Coates also showed a case of scleroderma in a man whose condition was greatly improved after vapour baths, thyroid extract, and sodium salicylate, and a patient with enlarged glands in the neck and a swelling behind the tonsil, considered to be due to tuberculosis, and not sarcoma, in view of its chronicity. His next case was one of enlarged liver and spleen in a young child with a strongly positive Wassermann reaction which had yielded but slowly to intravenous arsenic, injections of mercury, and iodides given by the month. A levulose test showed that there was considerable hepatic damage. He also exhibited a case of profuse rheumatic subcutaneous nodules and chorea in a girl aged 9.

Mr DUNCAN showed a case of osteomyelitis of the femur recently operated upon in the Royal United Hospital. In his opinion recovery was very largely due to the fact that it had been diagnosed so early by the medical practitioner who sent the patient to hospital.

Mr LEVIS showed a bad case of comminuted fracture of the upper half of the left femur, which had been treated in a remote part of the Scottish Highlands without the aid of X-rays. The first radiogram, taken five months later, showed an exceedingly good functional result with less than half an inch of shortening. He also presented a case of ulnar nerve paralysis following injury.

Dr DELICATI showed a case of early disseminated sclerosis.

Mr A. L. FULLER exhibited a crochet hook which had been inserted into the vagina and was ultimately recovered from the peritoneal cavity on abdominal section. He also brought a specimen removed from an infant 18 hours old, showing intestinal obstruction due to interruption of the lumen of the small intestine and non-development of the lower portion of the small intestine and colon.

HEATING AND VENTILATION OF SCHOOLS

IN A paper on "Methods of heating and ventilating schools and their influence on health," read before the Institution of Heating and Ventilating Engineers in London on October 9th, Dr H. M. VERNON, investigator for the Industrial Fatigue Research Board, said that the requisites of a good system were that it should keep the children sufficiently warm to enable them to reap the full benefit of the instruction being imparted to them. The air should not be so cold that their hands were numbed and their feet chilled, nor should it be so warm that they tended to become indolent and sleepy. If possible the temperature of the air at foot level should be equal to that at head level, if not above it, cool heads and warm feet were better than warm heads and cool feet, which most systems of heating tended to induce. There should be a fair degree of air movement, as moving air was more invigorating than stagnant air, and it was important that the air should not smell stuffy and unpleasant. It was desirable that these requisites should be obtained with the minimum of expense, and that the heating and ventilating arrangements should be of such a character that they were easily controlled and did not readily get out of order. Hence natural systems of ventilation were preferable to mechanical systems, provided they did their work properly, not only on most days of the year, but on all days, whether the outside air was very cold or very hot, and whether it was dead calm or blowing a gale.

Reviews.

DISEASES OF THE SCALP

DR SABOURAUD has now published his fourth volume of the *Maladies du Cuir Chevelu*. To the uninitiated it would seem an enormous—almost an impossible—undertaking to fill four volumes with an account of the diseases of the scalp alone. Sabouraud, however, states that the complete treatise which he has projected will extend to six, and his admirers will hope that he may be permitted to complete his allotted task. The fact is that the diseases of the scalp form for the author merely a text on which to hang his long and ingenious researches on all the infective diseases, fungoid or bacterial, which afflict the human cutis. Every student of dermatology is aware of the way in which he has cleared up the problems of ringworm and impetigo. The present volume¹ he has devoted to the pustular infections, and there is a certain amount of repetition of work which has already been recognized as established—for example, the streptococcal origin of impetigo contagiosa and the method (for which we are indebted to Griffon) of cultivating the streptococcus from the primary vesicles of the disease are all demonstrated over again. Thus, however, is necessary in order to complete the proper account of the disease from every aspect, as is fitting in a monumental treatise, moreover, we find here by far the best clinical description of impetigo in all its forms and variations that we have ever seen.

The tendency in general of Sabouraud's work is to show that many dermatoses hitherto unsuspected are due to bacterial infection, whether streptococcal or staphylococcal. Among others, that troublesome condition in which the scalp is universally inflamed and covered with greasy crusts more or less adherent to an erythematous and weeping base, the erythema extending beyond the margin of the hair, Sabouraud shows is probably a chronic streptococcal infection. In this volume the various staphylococcal dermatoses are also discussed in great detail, including the relations and distinctions between scrofula and acne necrotica. A puzzling point, noted but not explained, is the great tendency of scrofula to become chronic although the seat of the infection is extremely superficial. Another important subject dealt with in these pages is eczema. Sabouraud contrasts the polymorphic clinical appearances with the histological unity of the various forms. He is, however, as might be expected, chiefly concerned with the secondary microbic complications of that condition, a subject which, as he remarks, is difficult owing to the lack of specificity of the microbes living on the cutaneous surface and to the ease with which contamination takes place. Among other dermatoses discussed is the well-known pityriasis rosea, which he classes as one of the eczematides. But it is very difficult to do justice to the author's arguments within the compass of a short notice. Every dermatologist should read this book for himself. He will find it fascinating.

PSYCHOPATHOLOGY

A VOLUME entitled *Hypnosis*² is a translation from the German of a monograph by Professor PAUL SCHILDER and Dr OTTO KAUDERS of the Psychiatric Clinic, Vienna. We do not hear so much about hypnosis as a therapeutic weapon as formerly, but there can be but little doubt that it is useful in the treatment of a number of morbid conditions. The authors state that it has considerable value in the treatment even of organic disease, since apart from the question of whether psychotherapy can or cannot affect the fundamental trouble, it will be in a position to attain important results by influencing the individual attitude. The limitations and possibilities of hypnotic treatment are considered in organic illnesses, neurotic disturbances, drug addiction, sexual perversions, disturbances

of potency, and the psychoses. Apart from the question of therapeutics, the phenomena of hypnosis are themselves deserving of investigation. The authors here deal with their subject from both the biological and psychological standpoints, pointing out that in the last analysis the results of each of these methods of approach to the same problem should harmonize with one another. In successive chapters the following subjects are discussed: the effects of hypnosis, sleep and hypnosis, the state of consciousness of the hypnotized, the suggestive relation, the psycho-analytic theory of hypnosis, hypnosis as a social phenomenon, and the physiological theory of hypnosis. The psychopathologist will find this volume useful and informing. It provides a clear account of the most recent work on the subject with which it is concerned, and admirably combines biological conceptions with the recent conceptions of psycho-analysis.

At first sight it might appear somewhat unsuitable to include Dr LELY JELLIFFE's monograph on *Postencephalitic Respiratory Disorders*³ under the heading of "psychopathology." Disorders of behaviour are often observed as a sequel to acute lethargic encephalitis in children, but the remarkable respiratory disturbances occurring as post-encephalitic symptoms are generally regarded as conditioned by disease of the respiratory mechanism rather than by psychological factors. Dr Jelliffe does not deny that these respiratory syndromes are related to neurological lesions, he gives, indeed, an excellent summary of the various hypotheses which have been advanced to explain the respiratory disorders. He suggests, however, that these morbid reactions have also psychological determinants, and endeavours to interpret them along psycho-analytic lines as libidinous regressions to primary organ eroticism. In support of this thesis he gives case histories of two patients who derived apparent benefit from treatment by psycho-analysis. Thus for the author these respiratory symptoms present a problem which is at least as much the concern of the psychopathologist as of the organic neurologist. Dr Jelliffe writes obscurely, and it is doubtful if his formulations will carry conviction. At the same time the neurological sequelae of lethargic encephalitis do often appear to be influenced by psychological factors, and we should not be disposed to deny that psychogenesis plays a part in the causation of the respiratory symptoms or that psychotherapy may be helpful in their treatment. The book contains a valuable summary of the literature.

The thesis developed by Dr TRIGANT BURROW in his book on *The Social Basis of Consciousness*⁴ is somewhat difficult to grasp, but we believe it is not without significance. The basis of his essay, the writer explains, is precisely the recognition of the impossible breach between the condition of consciousness produced through a knowledge about feeling and the condition of consciousness that is the feeling itself between the state of mind that is commentative and the state of mind that is functioning. The former is objective, the latter subjective. The failure of our psychological methods to recognize this intrinsic distinction is, so Dr Burrow considers, the failure of our entire approach to the problems of mental and social disharmony. He feels, furthermore, that it is this unwitting substitution of the theory of human feelings for the unannotated experience of the experiences themselves as recorded in our interactive functioning as human beings that explains the impossibility of our present "method" of psycho-analysis. The author is of the opinion that to-day, under the impetus of psycho-analysis in its theoretical or vicarious form, we are carrying theory to the point of absurdity. He gives as an example the psycho-analytic theory of the nursery. Anxious young mothers are running about looking for texts which will serve them as guides in the love of their children. They

are diligently searching upon every hand for the latest approved theory of maternal love. And in response to the demand the popular literature is supplying them with full details. But there are no librettos of the nursery. Benedek's to motherhood are not to be had. The motherhood that is true is a subjective relationship, and it is only subjectively that it can be felt and understood. The case is cited of a patient whose mother, actuated by the theory of motherhood in its highest "scientific" interpretation, undertook to enlighten her upon the significance of sex. The mother having gathered courage for the performance of her maternal duty, delivered her message with a punctiliousness which from the point of view of technique was irreproachable. She spoke out of the strictest regard for the theory of motherhood. But unfortunately her theory left out of account an item that needs to be reckoned with—namely, the native simplicity of the consciousness of childhood. The woman spoke out of the theory of truth, but her child listened with the organic susceptibility of truth itself. The mother had not accepted within herself the actual significance of life, and so, in accordance with the formality of a theory, was viciously imposing its acceptance upon her child. But childish perception pierces the veil of pedagogic finesse. The rigid demeanour of her instructor readily disclosed the discrepancy between the verbal recital and the utter lack of conscious acceptance within herself. For the child, now a middle-aged woman, the moment was unforgettable. She had witnessed in her mother an outrage to organic truth, and the shock of that experience caused a psychic disunity between mother and child from which there resulted an introversion of personality that covered half a lifetime. And so, the author observes, while the theory of the nursery is from the point of view of theory wholly irreproachable, it is from the point of view of the nursery wholly absurd. This quotation will serve to indicate the kind of idea which it is the aim of the author to elaborate. The book is not easy reading, but it is full of psychological insight and in the opinion of the reviewer well repays careful study. Dr Burrow is clearly both enthusiastic and sincere

THE BLOOD PLASMA

In *The Blood Plasma in Health and Disease*,* one of the Monographs of Medical and Surgical Science, appearing under Professor R. J. S. McDowall's editorship, Dr J. W. Pickering, lecturer on haematology in King's College, University of London, has done good service by giving a full account of the present state of knowledge about this constituent of the blood, which has certainly attracted less general attention than the histological characters and embryological origin of the contained cells.

Though attractive on account of its potentialities, investigation of the blood plasma is, from its constantly changing character and constituents, beset with difficulties. William Harvey believed that the blood is a living tissue. In 1886 Woodbridge reiterated this hypothesis to the extent of saying that the blood plasma is a living fluid, this might be considered compatible with the view that the various proteins which can be obtained from it are artefacts. In suggesting general conclusions, Dr Pickering has wisely adopted the broad principle of doing so only when the physico-chemical and the biological phenomena point in the same direction, for example, he holds that normal plasma is not a mixture of different colloids, but a co-ordinated complex in which the less stable fractions (prothrombin and fibrinogen) are united to the more stable fractions (serum globulin and albumin), and so protected from the disruptive action of calcium ions, which is essential for the inception of blood clotting. It cannot yet be said to be established that the plasma is a living substance, or that thrombosis is allied to necrosis.

The immense subject of the coagulation of the blood is systematically and thoroughly gone into, the condition of the blood in anaphylactic and anaphylactoid states, in which there is plenty of pro-thrombin and an almost complete absence of thrombin, is dealt with, and in the chapter

on the blood of abnormal bleeders the characters of haemophilin and purpura haemorrhagica are fully considered. In an appendix there is a useful synopsis of the newer haemostatic agents. In conclusion, this well-documented monograph provides a valuable source of reference on a subject of much difficulty from a scientific aspect, and gives a considerable amount of practical information in regard to treatment.

VILLOUS TUMOUR OF THE RECTUM.

That the villous tumour of the rectum is a definite entity, with features that distinguish it from adenoma on the one hand and cancer on the other, is an opinion which is supported by both its clinical history and pathological anatomy. Dr ANDRÉ LAMBLING's book* gives a good description of the architecture of the villous tumour, its symptom-complex and proper treatment. The histories of his thirty-seven cases prove that the patient suffering from a villous tumour of the rectum is not likely to have his malady correctly diagnosed until he has become impatient with the palliative treatment offered for supposed colitis or haemorrhoids. This is all the more regrettable, since the surgical treatment is relatively simple and can offer a good prospect of permanent cure.

But while welcoming the general educational value of this book, we cannot pass without criticism the author's classification of the villous tumour into a benign variety and one which from the first is malignant. The more cautious, and also more likely, opinion—that every malignant villous tumour was at one time in a benign stage, and that any benign villous tumour may ultimately become malignant—is unshaken by any of the author's arguments. We do not feel that the slight histological differences he describes between the two types have any great importance and validity, and we must also point out that the pathologist is venturing into very disputed territory when he professes to diagnose malignancy in the absence of the one unequivocal sign—namely, intrusion of atypical epithelium into regions where it should not be.

ST BARTHOLOMEW'S HOSPITAL REPORTS

THE sixty-first volume of *St Bartholomew's Hospital Reports* opens with one of the historical articles which Sir D'Arcy Power writes so pleasantly and with authority, in this instance he deals with Harvey's physiciancy (1609-43) at the hospital. At that time the hospital was a series of detached buildings clustered round a central hall, and one of the houses was available for the physicians, a privilege which Harvey waived, and he therefore received no increased salary. Of the seventeen other articles the first seven deal with the respiratory system, Professor F. R. Fraser writes, out of the fullness of his recent Goulstonian Lectures, on dyspnoea, Drs F. G. Chaudler and J. V. Sparks set out with skiagrams the diagnosis of bronchiectasis with special reference to the value of lipiodol injections, and mention a special trocar and cannula, suggested by the senior of the two contributors, for the injection of lipiodol through the crico-thyroid membrane—a procedure remarkably free from serious discomfort. In his well-illustrated account of collapse therapy in unilateral basal bronchiectasis Mr J. E. H. Roberts urges early operation before the disease has become bilateral, as at this stage operation is reasonably safe and the prospects of considerable improvement or even cure are good. Artificial pneumothorax is considered in two articles by Drs F. H. Young and by R. Hilton, and Dr C. L. Hewer writes on anaesthesia in thoracic operations. Mr McMahon pleads for the early use of exercises after operation for emphysema. There are three articles dealing with the nervous system, Mr Just records two cases of cystic serous meningitis of the posterior fossa of otitic origin, Dr E. A. Carmichael of the Medical Professorial Unit gives a good account of the cerebro-spinal fluid in diseases of the ear and nose, and from the Surgical Professorial Unit Mr J. P. Ross records cases of intracranial injury

interesting on account of diagnostic features or treatment Mr J B Hume presents the report of the committee on the lead treatment of cancer, this investigation was carried out on twenty patients, but no evidence pointing to the value of the treatment was forthcoming, and the conclusions are highly unfavourable to this method of treatment Mr J P Hosford analyses 50 cases of acute osteomyelitis, 29, or 58 per cent, of these being due to *Staphylococcus aureus* infection Mr A E Roche contributes a valuable essay on torsion of the spermatic cord, of which he has had a rather unusual experience Mr R T Pynno writes on the therapeutic thrombosis of varicose veins from an experience of 75 cases treated by sclerosing injections of quinine and urethane The interest of the volume is kept up by the records of cases of rat-bite fever, heart-block, and femoral aneurysm

NOTES ON BOOKS

DR. O W BETHEA has taken the latest and most generally accepted information on the diagnosis and treatment of about one hundred of the most common medical diseases, and produced a volume entitled *Clinical Medicine*.⁸ He seeks especially to give such information as will be of use to the general practitioner working neither in the homes of the wealthy nor in the fully equipped hospital. From this point of view of practicality much of the book is very useful, although the detailed information about what gramophone records are most suitable for hysterical patients (p 575) seems a little absurd. The method of choosing certain diseases is open to criticism, for it results in such anomalies as hyperthyroidism being mentioned and cretinism omitted, the treatment of leprosy being discussed while syphilis is barely mentioned. The author states that unproven theory has been omitted almost entirely, and this explains why much of what is written on etiology is unsatisfactory. The section on acute endocarditis appears very muddled in this respect. Of bronchiectasis he says (p 94) 'This is a condition peculiar to middle life and old age. The condition is secondary to other diseases, such as tuberculosis and chronic bronchitis, and then gives an inaccurate picture of the etiology of this disorder. As a collection of clinical lectures (which, as the author admits, is what is here presented) the book has some value, but the general impression left is that the author has been too ambitious.

Dr JUDSON HERRICK, in the fourth edition of his well known and invaluable *Introduction to Neurology*,⁹ has rewritten the chapters on the cerebellum and on the sympathetic nervous system. The author does not approve of the terms parasympathetic, splanchnic, or autonomic, and does not use them. His visceral nervous system includes all nervous, whether central or peripheral, primarily serving the visceral functions. The sympathetic system is used as a topographic name for the peripheral ganglionated trunks and plexuses. The section dealing with the cerebellum is well done, especially considering the brevity of the chapter and the confusion of cerebellar nomenclature which exists.

Dr PHILIP LEWIN of Chicago has written *A Text book of Orthopaedic Surgery for Nurses*.¹⁰ There is, of course, nothing in it that may not be found in the standard works on orthopaedics, but the subject is briefly and simply dealt with, and no doubt the book will be welcomed by those for whom it is intended, and the nurses who master it may hope to feel themselves in a position to appreciate and perhaps to criticize the diagnosis and treatment of the surgeons with whom they work.

Physical education seems, at all events in America, to be developing into a science, and it is not surprising therefore, to find that the Teachers College of Columbia University, New York, already has a professorial chair in the subject, and that the professor, Dr I F WILLIAMS, has felt called upon to publish a book, *The Principles of Physical Education*,¹¹ on the scientific facts underlying physical education, together with its developmental, preventive, and educational aspects. Unfortunately Dr Williams is a ponderous writer, with a confirmed

habit of repeating himself on every other page. He cannot get away for a moment from his main thesis—that the function of physical education is primarily education, and that it is not a method for securing health. He is contemptuous of Swedish exercises, calisthenics, and other formal exercises imported into America by immigrants. Such exercises were suitable, perhaps, for effete, militarized communities in Europe, they are not compatible with the ideals of a free democratic society. He wants a program for developing educational activities of a natural kind out of doors, rather than therapeutic corrective exercises in the classrooms of the school. He dislikes the assumption that the child, on entering school, does not know how to breathe properly, and needs oxygen and breathing exercises. There is probably some truth, if not good English, in his statement that the majority of children enter on their teens with round backs, and in most of them it has disappeared in the next half dozen years. For the development of

certain motor habits that reflect neuron organizations in the nervous system, Dr Williams advocates games, beginning with those that are related to the individual's instinctive organization, such as running, jumping, throwing, hanging by the arms, and so on. Later on education will proceed to swimming, football, baseball, camping, fishing and hiking. In this country the need for a professor of physical education has hardly arisen as yet, but it appears that the authorities of our primary schools agree with the author that for physical development games are preferable to formal hygienic exercises.

The fourth edition of the *Chemical Encyclopaedia*¹² by C T KINGZETT, is some 200 pages larger than the previous one, which appeared in 1924. The book is an epitomized digest of chemistry and its industrial applications. The bibliographical side has received special attention, and an immense amount of condensed information is made available. There is little doubt that the popularity of this edition will exceed even that of its predecessors.

PREPARATIONS AND APPLIANCES

A 'NON-SKID' GUILLOTINE HEAD

MR O POPPER F.R.C.S., first assistant Royal Ear Hospital, University College Hospital, writes. It is a remarkable fact that perfect enucleation of tonsils by the guillotine fails so often even if immaculate technique is not infallible. One sees failures ranging from the small piece of capsule which has been 'buttonholed' to an almost complete tonsil remaining as rests in one or both tonsillar fossae. Complete rotation or inversion of the tonsil through the guillotine ring is the secret of perfect enucleation. When this has been effected and the new position of the tonsil is sustained by counter pressure the rest of the operation becomes automatic. During this inversion the end of the guillotine head becomes the fulcrum around which the tonsil is rotated and the instrument is held rigid. Here there is a great tendency for the lateral and posterior portion of the tonsil to slip back or 'skid' out of the ring, especially where the tonsil is flat, buried or fibrous—the so-called 'difficult' case. Particularly is this liability great when the blade is being driven home and finger pressure above the tonsil is slightly eased to avoid the blade. Furthermore, where the guillotine head is thin and frail it invariably becomes bent or otherwise injured very early in its career. In consequence the blade does not go home completely and part of the tonsil or capsule slips back through the gap. A more robust type of end is therefore indicated where the surgeon does not care to carry a large selection of guillotines or to be obliged to supervise his instrument most carefully especially when it is being thrown into the sterilizer. To counteract the tendency of the tonsil to skid or slip back I have found the guillotine head illustrated most effective. The inner ring margin at the upper surface is sharp and serrated in its distal half, the projections being miniature chisels which are undercut, note that this edge bounds the opening of the ring and is therefore not quite at the end of the head. The guillotine head is placed behind the tonsil in the usual way. As the tonsil is pressed over this edge it is securely anchored and cannot slip back. There are many types of excellent guillotines and the selection is a matter of individual taste with regard to such characteristics as weight, handle and grip. I would recommend the incorporation of the 'non-skid' head so as further to increase its efficiency. The advantages are briefly: (1) There is no skidding; it anchors the tonsil during the most important part of the operation. (2) It does not interfere with the usual technique of the operation. (3) It occupies no extra space and can be incorporated in the instrument usually employed. (4) It makes enucleation easy in the difficult cases. (5) The head is robust.

LUNACY AND MENTAL DEFICIENCY

THE BOARD OF CONTROL'S REPORT FOR 1927

IN the fourteenth annual report of the Board of Control,¹ of which the mental deficiency section was noticed in our last issue (p. 670), regret is expressed that it has not yet been found practicable to give effect to the recommendations of the Royal Commission on Lunacy and Mental Disorder and to introduce legislation to facilitate early treatment of mental disorders. It is a pity that, so far, lack of parliamentary time has prevented a matter of such urgency from receiving due consideration. At present the great majority of victims of mental disorder cannot obtain institutional treatment until they have been certified insane. This means in effect, that they cannot receive the advantages offered by the modern development of psychological medicine at the stage of their malady when they can best derive benefit from them. The Board expresses the view that adequate treatment of the early mental case demands a relaxation of the legal necessity for certification as a pre-requisite of treatment, and a reconsideration of the extent to which, in such cases, the intervention of a judicial authority is essential.

The Problem of Accommodation

The problem of accommodation is becoming each year more acute. The number of notified and insane persons under care in England and Wales on January 1st, 1928, was 138,293, an advance of 1,667 over the number in the preceding year. The average annual increase for the past five years has been 2,403. These figures must not be taken to imply an increase in the general incidence of mental disorder; they represent merely the net balance of admissions into institutions over the deaths and discharges. But in January, 1928, the total vacant accommodation in all the county and borough mental hospitals was only 1,570—a sufficient indication of the present critical situation. The reopening of the Fwell Colony in 1927, and numerous further small additions and rearrangements, provide for a further total of 1,326 patients, and it is estimated that at the end of the present year the number will have been increased by another 1,250. Such small additions, however, do very little towards easing the general situation, and energetic measures are necessary if serious overcrowding is to be prevented. So far only two authorities, Middlesex and Swansea and Merthyr Tydfil, are proposing to make good the deficiency by erecting new institutions. The erection of detached nurses' homes, now in progress, is welcomed not only as a measure relieving the strain on existing accommodation, but as one which, by attracting a better type of probationer, will enable the Board to raise the status of the mental nurse and the standard of mental nursing.

Movement of Patients

The statistical survey under this head excludes patients in Poor Law institutions and those receiving outdoor relief, detailed information about these classes not being available. The daily average number of certified patients increased from 115,166 in 1926 to 117,327 in 1927, the ratio of admissions per 10,000 of the adult population (aged 16 and upwards) was 7.66, a progressive decline being shown in the table of ratios from 1921 to 1927. The recovery rate, calculated upon the direct admissions, was 31.43 per cent, though, if to the number of recoveries are added those patients classified as discharged and not now insane, and those discharged after escape, the absolute discharges from reception orders during the year were 48.3 per cent of the direct admissions. The death rate was 7.49 per cent of the daily average number resident, the first rise in this rate since 1922.

¹ Lunacy and Mental Deficiency, Fourteenth Annual Report of the Board of Control for the year 1927. Parts I and II. London: H.M. Stationery Office or through any bookseller, 1928. Part I 1s. 9d. net. Part II 9s. net.

Infections and Allied Diseases

During the year there were 127 cases of enteric fever, with 30 deaths. It is gratifying to note that prophylactic inoculation against the enteric group of diseases is being used increasingly among both patients and staff. In the cases of a few carriers excision of the gall bladder has been effected, and their excreta have thereby been freed from the typhoid bacillus. An important relation between dysentery and the group of cases classified as severe diarrhoea is indicated in the report. It has been shown that the latter cases occur concurrently with outbreaks of dysentery, and that perfection of laboratory technique and the speedy plating out of specimens often result in the transference of these cases to the dysentery group. In 1927 there were 515 cases of dysentery, with 76 deaths. Reduction of the incidence rate of pulmonary tuberculosis has suffered a slight check, there being only 44 fewer cases this year, as against 185 the year previous. This may perhaps be accounted for by the far greater outbreak of influenza and acute pulmonary conditions in 1927 than in 1926, actually 5,503 cases as against 1,022.

Royal Bethlem Hospital

The revised scheme and plans for a new Bethlem Hospital have been approved by the Board. These plans embody the most modern principles of construction, and the hospital will consist of a number of detached buildings to allow of suitable classification and housing of patients. Provision is made for pathological, bacteriological, psychological, dental, electrical, and x-ray departments, as well as for an operating room. There will be accommodation for 300 patients.

Increased Suicide Rate

The granting of parole, which continues to be a great feature in good mental hospital administration, has been associated with an increased suicide rate, this being 69 as against the next highest record of 55. But such deaths among patients enjoying this liberty should not, in the Board's view, weigh against the great benefit gained by the 9,000 patients allowed parole within the hospital grounds and by the 3,200 who, in addition, can go unaccompanied for walks beyond the hospital limits.

Mechanical Restraint

The commemoration of the Pinel centenary has been made the occasion for an historical survey of the evolution of mechanical restraint in mental hospitals. Tribute is paid, not only to Philippe Pinel, but to the layman, Mr. William Inke, who inspired the foundation of the Retreat—the first institute in this country for the treatment of mental disorders without unnecessary restraint. The Board points out that the amount of physical restraint is so negligible that, although regular returns of such use are requisitioned, it finds in practice that all reference to the matter is frequently omitted from its entries.

Treatment of Post-encephalitis

The first part of the report concludes with a statement of the great need for an industrial home or colony for some few hundred juvenile post-encephalitic patients who might there secure tactful handling, clinical and laboratory investigations, occupations of interest, and remedial physical exercises with orthopaedic treatment. The hope is expressed that systematic observations of treatment of all types of mental disorder may be kept so that greater precision in prescribing such treatment may ultimately be attained.

Research and Statistics

The second part of the report opens with a brief summary of the scientific research work that has been carried out in mental hospitals during 1927. This is followed by seven appendices devoted to a series of statistical tables giving the annual returns of insane persons in institutions, the annual returns of voluntary boarders, and the entries by commissioners at the various types of mental hospitals and licensed houses. It contains also complete lists of institutions for the insane and for mental defectives.

British Medical Journal.

SATURDAY, OCTOBER 20TH, 1928

THE HARVEIAN ORATION

THE task of the Harveian Orator becomes, almost necessarily, more and more difficult in each succeeding year. The latest of a long series of students and essayists, he is set a text which has been expounded again and again, and to this well worn topic he must strive to bring, if haply he may, some new light or some new suggestion. On the present occasion this inevitable stress must have been heightened by the fact that the Royal College of Physicians of London, to which the Oration is addressed, heard during the recent tercentenary celebrations many informed and eloquent tributes paid to the memory of the very man in whose honour the Harveian Orator is himself called into existence. To be summoned to provide a contribution capable of arresting the attention of an audience that has already listened to much discourse is a large demand presented in decidedly trying circumstances. Not unexpectedly Sir Humphry Rolleston has met the occasion in a worthy fashion. His Oration possesses an individual and distinctive quality which will certainly secure for it a recognized position among the many tributes paid to the character and work of the great physician whose memory it is alike the duty and the pride of the Harveian Orator to honour. In a brief phrase the Oration may be said to define our existing knowledge of the physiology and pathology of the cardiovascular apparatus, and to trace the steps by which this knowledge has been attained.

On many previous occasions the Harveian Orator of the day has not unnaturally found a text in the character or work or methods of William Harvey himself, or in the personal, academic or philosophical relations associated with Harvey's name and time, and the series now at the 272nd number includes many stimulating and fascinating studies of this order. Sir Humphry Rolleston has utilized his opportunity in a somewhat different fashion. His starting point, indeed is Harvey, but his theme is the story of the workers who touched more or less by the inspiration of the Master have added their individual contributions to the body of physiological and medical doctrine that has its foundations in Harvey's great discovery. To recall these contributions and their authors is to witness to the praise of him who made so much possible and indeed inevitable. One purpose of the Oration as desired by Harvey himself is to commemorate all the Benefactors of the College and as happily argued by the present Orator can any benefaction be more welcome than new and true knowledge? The list of those now commemorated is both a long and a varied one, and its compilation has evidently meant much care and time and devoted industry. Doubtless there are others who have no memorial but broadly we have here a carefully summarized presentation, extending over some three centuries of the thought and study and experience of physicians and physiologists who, provided with certain great fundamental truths by the work of Harvey, have made each for himself some more or less important addition to the growing body of knowledge. If the beginning was a great and new departure it was also an inspiration for the

future, and in this respect, as Sir Humphry Rolleston shows, it has not been wanting in fruitful success.

A reader of the Oration as it appears in our opening pages this week can scarcely fail to be impressed by the intricacies and complexities of what at first sight might well appear to be a comparatively simple and straightforward physiological problem. The heart and blood vessels have often been presented as a mechanism governed by well defined physical laws, and roughly and leaving aside the nature of cardiac force, the picture is not an untrue one. But how conspicuously has investigation shown that this apparent simplicity hides a thousand complexities of detail and how gradual has been the recognition and interpretation of the problems which such details involve! To-day's textbooks of physiology read strangely to those who were medical students but a few short years ago, and this statement applies even to such large issues as the fashion of cardiac action and the part played by the capillaries in the working of the circulatory mechanism. Undifferentiated muscular masses stirred to activity by nerve currents, much in the manner of the skeletal muscles, have disappeared in favour of specialized groups charged with individual functions and competent for automatic action, while the capillaries, formerly regarded as mere passive channels, are now seen to be vessels attuned to vary actively in calibre in accordance with local needs and further, such activity is found to be essential to the efficiency—and, indeed, to the very existence—of the circulatory process. More and more penetrating becomes the analysis and who will say that even now the final word has been spoken on every aspect of such a central problem as the physiology of the circulatory mechanism? To each generation completeness may seem to have been attained but every to-morrow brings its new and disturbing challenge.

If what has just been said is true on the plane of physiology, it is true with emphasis when pathological disturbances of the circulation have to be considered. Here the problems are more intricate and more complex and the methods necessary for their exact study are but of yesterday. Simple, direct clinical study, as Sir Humphry Rolleston notes, while observing and recording many facts, has largely failed, though cultivated diligently by highly competent minds, to find the scientific meanings of the facts and not infrequently has been associated with speculative views that time has contradicted. It is in the nature of things that experiments, made in circumstances where conditions can be commanded and controls established, will give confident answers to precise questions in a fashion that cannot be expected from the processes of disease as these present themselves to the student of clinical medicine. Thus the experimenter may seem to secure what the physician has failed to accomplish. The latter however, is not without his consolations. After all the purpose of the physician is not at all events primarily the establishment of scientific generalizations but the care of the individual patient and when he accomplishes this appealing task he more than justifies his existence, though this is not to say that he has not often cultivated and reached wider ambitions. Indeed, Sir Humphry Rolleston in his comprehensive recital, tells us of many such ambitions and many such triumphs and these not unworthy at least in spirit, to be quoted in the series of which Harvey himself was the true begueter.

For my knowledge which will contribute to his efficiency—whether provided by the experimental or

the doctrinal physiologist—the physician is, of course, duly grateful, and he may reflect, not without satisfaction, that he has on not a few occasions discovered problems for his more exact colleagues to solve, and has even thrown helpful light on these problems. The Harveian Oration for 1928 illustrates these propositions, and emphasizes both the inseparable union between physiology and medicine, and also their mutual helpfulness. Each in its own way contributes something to the common aim—the discovery of truth and the prevention and cure of disease.

BACKACHE.

THE importance of the symptom long known as backache, and more recently in the United States called low back pain, has won recognition very slowly. That it has done so at all is chiefly due to the Boston group of orthopaedic surgeons, and especially to Goldthwait, who for years has upheld the view that, although very many cases of chronic pain in the lumbo sacral region are due to faulty posture, many others are the result of serious anatomical derangement of the bones and joints of the spine and pelvis. Of late years this view of the pathology of back pain has gained ground in the United States, and more slowly and cautiously in this country, but it cannot yet be asserted that the majority of British surgeons accept the frequency of such an injury as subluxation of the sacro iliac joint as a proven fact.

This attitude of caution and scepticism has much justification, for it is extremely difficult to demonstrate the existence of displacement of bones in such cases, and even more difficult for the surgeon or pathologist to satisfy himself that there is abnormal mobility in the sacro iliac joint. In the more accessible joints, such as the knee or the ankle, the reality of the offending lesion is as a rule easily ascertained, especially with the aid of x rays, for the articulation is not thickly covered with soft parts, and offers itself to radiations directed from any or every point of the periphery. In the lumbo sacral region the prospect is very different, for the parts are deeply seated, cannot be explored by x rays except on a few aspects, and the bones are peculiarly liable to developmental variations which may mislead all but the most experienced. Moreover, it has seemed to many readers of accounts of the diagnosis and relief of some supposed cases of sacro iliac strain or subluxation that the means employed to effect a cure were singularly disproportionate to the gravity of the supposed lesion. But in other cases, in which the gravity of the symptoms and the certainty or great probability of joint or bone injury justified operative intervention, an arthrodesis with or without a fixative bone graft effected a cure.

In opening the discussion, at the Annual Meeting of the British Medical Association at Cardiff, on low backache and sciatica, Mr W. A. Cochrane of Edinburgh (whose paper appears at page 696 this week) did not discuss such operations, but found plenty of material for debate in the diagnosis and bloodless treatment of the numerous cases, chiefly of injury, which too often become chronic and involve much suffering and prolonged disability. In this connexion he made the interesting statement that in one large works back strains and injuries of this type are responsible for 20 per cent of all accidents. Backache of traumatic origin may be the result of tearing of muscle or of muscular attachment, of ligament with or without joint injury, or of fracture of bone, or, in a severe injury of all these combined. Mr Cochrane did well to emphasize the frequency of often unsuspected crush fractures of

vertebrae, and to insist on the need of skilful use of x rays for their detection. It is not to be forgotten, too, that sciatica, which he included in his subject, as well as lumbago, may attack its victim with lightning like suddenness, thus earning the German name of *Hexenschuss*, or 'witches' shot'. It is conceivable that if such an attack were to occur during a considerable effort made by the patient its effects might be wrongly attributed to injury.

Attention has been lately concentrated so much upon backache resulting from sudden injury that there may be a danger of neglecting the consideration of those forms which follow slowly cumulative strain. Faulty posture is responsible for some of these cases, as Goldthwait has so clearly shown, and such posture is more often the result of defective muscle tone than the cause of it. With improvement of the general physical condition and training of muscle groups postural tone can be restored and backache cured. Another form, which Mr P. Jenner Verrall described and discussed at Cardiff, is the backache of pregnant women, which too often persists after pregnancy is at an end. The sacro iliac and also the lumbo sacral joints are subject to severe strains in even a normal pregnancy, and it is well known that the mobility of all the pelvic articulations is thereby increased. If from insufficient recumbency after labour, or want of recuperative power, the joints are not restored to their ordinary stability, much chronic trouble will persist. The proper treatment of these and other forms of low backache was well insisted upon by him and by others who took part in the discussion.

In an illuminating essay in the *Robert Jones Birthday Volume* Dr R. B. Osgood of Boston has recalled attention to the importance of chronic constipation as a cause of so called sacro iliac arthritis. The work which he has done on backache and allied troubles is well known, and his reputation gives weight to his statements. He gives details of four cases, which are the more striking because none of the patients was over 36 years of age, and one of them was a university athlete. All these were cured by relieving the intestinal overloading, which may, as Dr Osgood points out, exist in spite of daily apparently normal evacuations, and can only be detected by barium meals and frequent radiological inspections.

Less than a month before the discussion at Cardiff the seventy seventh annual session of the American Medical Association was held at Minneapolis, when Dr John T. O'Ferrall of New Orleans read a paper on low back pain,¹ in which he stated his opinion that too much attention had lately been paid to the effects, or supposed effects, of bone abnormalities, and not enough to injuries of the soft parts. In particular, he holds that the lumbo sacral joint is more often affected by injury than the sacro iliac, and that this consists in a strain of the ligaments of this joint. He agrees, however, with Dr Osgood in laying stress on the important part played by constipation in many cases of backache. It was well that this important subject should have been discussed at the annual meetings of both associations, and it is to be hoped that the publication of Mr Cochrane's paper will attract the attention of all British surgeons to the importance of the problem of the causation and cure of backache, and of the need for very careful and thorough investigation. When all has been done that can be done, we think it is likely to be found that there are many causes and many cures for these symptoms, but that the most important means of treatment is Hiltonian rest in the earliest stage.

THE DISINFECTANT VALUE OF MERCUROCHROME.

The rapid and efficient disinfection of the skin preparatory to operations is of such great importance in surgery that it is very desirable to possess accurate information concerning the relative efficacy of the procedures at present employed. Tincture of iodine had been in general use for this purpose for many years, but mercurochrome has been recommended recently as a more convenient and efficient disinfectant. The relative merits of these preparations have been studied recently by American workers, but unfortunately their conclusions are contradictory. Simmons,¹ working in the Army Medical School, inbred bacterial cultures into the skin of rabbits, and one hour later painted on to a series of similar areas aqueous and alcoholic solutions of mercurochrome and tincture of iodine. After an interval of from five to twenty minutes cultures were made from the surface of the skin, and also from scrapings from the deeper layers of the skin. Reddish and Drake,² working in Baltimore, performed almost identical experiments with the same solutions, except that they used weaker suspensions and that they washed then skin scrapings from plating them out. Curiously enough, these two sets of closely similar experiments gave diametrically opposite results. Simmons reports that 2 per cent mercurochrome in aqueous solution was not effective in disinfection of the unbroken skin, and that the 2 per cent aqueous alcohol acetone solution was only slightly better; moreover, he found that 3.5 per cent alcoholic solution of iodine was more actively bactericidal on unbroken skin than any of the mercurochrome solutions tested, and that tincture of iodine (U.S.P.) was far superior to any of those solutions for use on the unbroken skin. Reddish and Drake found that tincture of iodine and 2 per cent mercurochrome were equally effective, and concluded that mercurochrome in aqueous alcohol acetone solution was far more desirable than tincture of iodine for preoperative skin disinfection. In the same number of the *Journal of the American Medical Association*, Captain Rodriguez³ of the United States Army Dental Corps reported on mercurochrome and iodine in the disinfection of the mucous membrane of the mouth and concluded that mercurochrome was too feeble an antiseptic to be used safely as a surface disinfectant of the oral mucous membranes, but that 1.75 per cent iodine in glycerin was an effective germicide. A gallant attempt is made, in an editorial in the issue of the *Journal of the American Medical Association* in which this work appeared to find some explanation for this remarkable discrepancy in experimental results. The dispute is of a type that not uncommonly arises when the merits of an old-established drug are compared with those of a new substance. The results, however, appear completely irreconcilable, and it is to be hoped that other workers will repeat the experiments, for the relative merit of tincture of iodine and mercurochrome as skin disinfectants is of considerable practical importance.

THE LEAGUE OF NATIONS AND OPIUM

THE Geneva Opium Convention of 1925 came into force on September 25th, 1928, it is now incumbent on the Council of the League of Nations to appoint a Central Board within three months, to undertake the prescribed duties in regard to international commerce in the substances covered by the Convention, and to arrange for the organization and working of the board and its staff. Provision had been made for the United States Government to appoint one member of the new Central Board, but, in accord with the attitude taken up at the Geneva conferences in 1924-25, from which the United States delegates eventually with-

dren, the Council's invitation to participate in the selection of the board has been declined. The reason assigned for this refusal is the inadequacy of the Geneva Convention in regard to limiting the production of raw opium and coking leaves to the medicinal and scientific needs of the world. The United States Government holds that until there can be devised some substitute for the Hague Convention more satisfactory than the Geneva Convention, the eradication of the abuse of narcotic drugs would be more likely to be achieved by strict observance of the provisions of the Hague Convention. The United States will, however, in addition to observing its obligations under the Hague Convention, endeavour to furnish information as the permanent Central Board may request. Meanwhile, at the recent meetings of the Council and Assembly of the League, considerable discussion was aroused by the proposal of the British Government mentioned in the *Journal of September 29th* (p. 578) to set up a fresh commission of inquiry to examine the conditions of opium smoking and the illicit traffic in opium in the Far East. Objection was taken by representatives of several countries to the expense with which such an inquiry would burden the League, and at first the proposal had a very cool reception. When the French representative urged that the investigation should include China, the Chinese delegate demurred unless, indeed, the inquiry should cover the commerce in derivatives of opium exported to China from European countries. This inquiry is deemed essential in view of the decision to hold a further conference on opium smoking in the Far East in 1929. It will be remembered that the Hague Convention of 1912 bound the contracting Powers to bring about the gradual and effective "suppression" of the commerce in opium "prepared" for smoking wherever the Geneva Convention made such suppression dependent on the prior elimination of smuggling. There can be no doubt that the trade in prepared opium, both licit and illicit, continues to flourish in the Far East. The Federated Malay States, the Straits Settlements, Borneo, and British North Borneo derive no inconsiderable percentage of their revenues from opium smoking. Further inquiry may be necessary, but action in accord with treaty engagements would seem to be urgently required.

CHANGES IN THE INCIDENCE OF DISEASE.

It is a commonplace that the incidence and the nature of diseases are slowly but continuously changing. To some extent the process appears to be evolutionary in the disease or the disease-producing organisms, sometimes, it seems, a new disease appears, as witness encephalitis lethargica (if, indeed, that is a "new" disease), but more frequently the cause of the change lies in the conditions under which we live. The progress of sanitation and the increasing activities of the public health services, the better education of the medical profession, and—what is more apparent—of the general public to appreciate the importance of the earlier signs of disease and the increased efficiency of our prophylactic precautions and therapeutic methods have combined together to effect great alterations in the statistics of national health, and in many cases have changed the complexion, and in some cases almost eliminated the incidence, of diseases which, only a few decades ago, might well be termed national scourges. In his presidential address to the Section of Ophthalmology of the Royal Society of Medicine Mr. Cyril H. Walker dwelt on this general trend of diseases as it has been apparent in diseases of the eye in his own locality of Bristol. He refuted the idea that the varieties of eye troubles found in an ophthalmic clinic are more or less constant, and that common diseases will always remain so, and showed that the incidence of some ophthalmic diseases

¹ J. S. Simmons. *Journ. Amer. Med. Assoc.* September 8th 1928 p. 704.
² G. F. Reddish and W. E. Drake. *Ibid.* p. 712.
³ F. E. Rodriguez. *Ibid.* p. 708.

is undoubtedly changing, and changing even more rapidly now than in the past. Leprosy, the scourge of the Middle Ages, has disappeared from England completely, largely through efficient measures of segregation of those afflicted with it. The most obvious change in comparatively recent times, of course, is the modern absence of blindness from small-pox. About 1840 half the inmates of the Bristol Blind Asylum owed their blindness to this disease, but it is now more than thirty years since any admission into the asylum could be traced to this source. The cause of this change is evident, it is due to the prophylactic influence of vaccination. A similar cause—the adoption of the prophylactic Ciedé treatment of the instillation of nitrate of silver into the eyes of newborn babies by nurses and midwives generally—has wrought a comparable though not as complete a revolution in the incidence of ophthalmia neonatorum, a disease until recently one of the most prolific causes of blindness. Since compulsory notification of this disease has been introduced its incidence has fallen steadily all over England. Mr Walker remarked that in his district there were 119 notifications in 1922 and only 39 in 1927, while the percentage of pupils who were in the Bristol School for the Blind on account of this disease was only about one-quarter of what it was fifty years ago, and many of these had so little visual defect that they would undoubtedly at that time have been educated in an ordinary school. A direct consequence of this was that gross corneal opacities and leucomata were less frequent. More efficient early treatment had made syphilitic nitis a rare disease, and similarly had lessened the incidence of interstitial keratitis. Mr Walker, indeed, made bold to prophesy that the latter, common to-day, would in ten years' time also become rare. So, too, with the ocular complications of diphtheria—the conjunctivitis, the ocular palsies, and so on—are almost unknown to-day. More efficient treatment and education as to its contagiousness have undoubtedly lessened the ravages, although by no means eliminated the incidence, of trachoma. Mr Treacher Collins in 1925 recorded that, while in 1874 42 per cent of the children in the Poor Law schools of London were found to be trachomatous, in 1924 the number of cases was 8. Such is the satisfactory result of the introduction of prophylactic measures, the early diagnosis and efficient treatment of early cases, the team-work of the profession, and the constant vigilance of medical officers of health and local authorities. Social conditions, the evils of slumdom and overcrowding, and the factor of a deficient or irrational dietary have a profound influence on the manifestations of disease. Dirt and neglect are the parents of conjunctivitis and blepharitis, sunlessness and improper feeding, of phlyctenular disease. As social conditions change, so also do these diseases. The squalor which was rife thirty years ago is not so evident to-day, the improved conditions of the poor since the war, and the shepherding action of the educational authorities, with their periodical inspections and the elimination of dental and tonsillar and adenoid infection, have undoubtedly lowered the incidence of these among the younger population.

THYROID DISEASE IN NEW ZEALAND

THE apparent, if not actual, increase of thyroid disease has stimulated investigation in various parts of the world, and the *Proceedings of the University of Otago Medical School*,¹ edited by Professor D. W. Carmalt-Jones, formerly on the staff of the Westminster Hospital, contains five reprints of articles, previously published elsewhere, on various aspects of the subject as visible in New Zealand. The first article, by Professor Carmalt-Jones, is a paper read before the

Royal Society of Medicine as recently as May last. This in effect gives a summary of the conclusions of the inquiry, which are set out in detail by Dr Hercus and his co-workers and by Dr A. M. Drennan, the professors of bacteriology and pathology respectively in the University of Otago, Dunedin. Simple and toxic goitre are frequent in New Zealand, and trout and lambs are also affected. The etiology of simple goitre is discussed with reference both to the results obtained in New Zealand and those which Dr Marine in North America and Colonel McCarrison in India have reported. From nearly 500 analyses of the soil for the iodine content, and of surveys with the same object of foods, and from the examination of school children, it appears that the incidence of endemic goitre in New Zealand varies inversely as the amount of iodine in the soil, and that the important factor is the iodine content of the food. Though infections are admitted to favour goitre, the influence of the water supply is found to be very small. According to Professor Carmalt-Jones, there are good grounds for the view that exophthalmos is an accidental event in toxic goitre, generally occurring in the hyperplastic and also in the graver cases, but no more essential to any one form of thyroid disease than is ophthalmoplegia in the diagnosis of tabes, he therefore includes under the term "toxic goitre" cases of Graves's disease and all cases with tachycardia, tremor, and increased basal metabolic rate. The prophylactic treatment by iodine and the danger of thus producing toxic goitre are carefully considered, and good results are reported from the daily administration of very minute quantities of potassium iodide in table salt, as had previously been done in Switzerland and North America. In February, 1924, at the annual congress of the New Zealand Branch of the British Medical Association, a resolution was passed urging the Government to introduce in endemic areas the use of "iodized salt," containing 1 part of potassium iodide in 250,000 parts of salt.

CO-OPERATIVE MEDICAL SERVICES

THE current issue of the *Co-operative Review* contains an article entitled "A co-operative medical service," by Mr N. J. Morton, to which attention may be directed as an example of proposals made from time to time, seriously enough and with the best intentions, to establish medical services in extension of, or intimately associated with, the national health insurance system, without apparently, the slightest knowledge of, or regard for, the opinions of the medical profession, and with very little appreciation of practical realities or established facts. Mr Morton has had some experience as a member of the West Riding Insurance Committee, but he has allowed his zeal as he secretary of an industrial co-operative society to outrun that experience. Among the proposals he makes as part of his co-operative scheme to provide a medical service similar to that established by the National Health Insurance Acts for "the wives and children of the workers at comparatively little extra cost," are some which are of at least questionable legality, some which would almost certainly involve the removal from the insurance medical list or from the *Medical Register* of the name of the participating practitioner, and others which would merely result in establishing once more the conditions of that old "club practice" from which the profession almost entirely rid itself on the enactment of the national health insurance scheme. A few of Mr Morton's proposals may be mentioned, and little further comment seems necessary: (1) A doctor for members of the society would be engaged "in the same way as we engage a manager, a secretary, or a chemist. There is a lot of prejudice in the case of doctors. It is time we were done with such prejudice.

The doctor would be under the committee of management of a society, and if he did not do the right thing

¹ *Proceedings of the University of Otago Medical School*, No. 5, 1928. Goitre Number. Edited by D. W. Carmalt-Jones, MD, FRCP, Dunedin N.Z. University of Otago.

he would be treated in the same way as other employees who do not give satisfaction" (2) "There would be no reason whatever why all members who are insured persons should not choose our 'co-operative' doctor, whose name would be on the panel in the ordinary way" "But in order to have as many as possible of our members who are already insured persons in the scheme, and so that the whole family may have the same doctor, I would make a rebate of 6s per person per year to each family whose insured members nominated our doctor as panel doctor, up to the number of two in each household"—that is, insured persons would be canvassed in favour of a particular doctor, with a monetary consideration as one inducement (3) "The doctor would receive for his entire services a really salary, and any income derived under the National Health Insurance Act as a panel doctor would be refunded to the society, so that in all probability we should augment our income by 9s 6d per head for all the members who had nominated our doctor as their panel doctor" This is reiterated and extended thus "Any earnings as an ordinary medical practitioner, or as a panel doctor, would come into the society's funds" The business astuteness of this bargain (assuming a practitioner willing to enter into it) need not be questioned The statistical statements and financial judgements of the scheme will not bear detailed scrutiny Thus there is an error in the statement of the number of insured persons a practitioner is allowed to accept, and the calculation of the number of items of attendance required is unreliable (4) For attendance on 6,000 individuals, "supposing we had to pay £750 for a really capable man, and £450 for his assistant," this "would still leave £535 per annum for administration expenses and extra services", but then the salary need not be fixed "on the basis of what a doctor who had built up an extensive practice might be making Hundreds of capable doctors have not an extensive practice I am informed that in the medical papers advertisements appear regularly for doctors at a salary of about £400 to £500 a year" Our profession may not be opposed to an extension of the benefits of national health insurance to the dependants of certain insured persons under proper auspices and conditions, but such a scheme as that outlined is a mere travesty of anything that could even begin to be considered by the law, the administration, or the medical profession

INDUSTRIAL HEALTH EDUCATION

SIR HUMPHRY ROLLESTON has accepted the position of honorary president of the Industrial Health Education Society, a body which had its origin in Scotland, but which has now for some time been established in London The society promotes its objects largely by the provision of health talks and the promotion of free discussion among industrial workers, the only questions which may not be raised at its meetings being those that relate to disputes between employers and employed A considerable amount of work has been carried out in the mining areas, and the Central Miners' Welfare Committee has made a grant of £500 for the extension of the society's operations into districts not yet covered A grant of the same amount has been made by the South Wales Welfare Committee, and others—in several cases repeating earlier assistance—in miners' welfare committees in Lancashire, Durham, and Northumberland Special attention has been given to bakers' dermatitis, and to health conditions in the boot and shoe industry, in the cotton industry, and in other trades The society has also published several leaflets on certain diseases, and is now extending the scope of its propaganda to include exhibitions of health films A notable feature of its meetings has been the lively interest displayed by workers in health matters, the invitation to

raise questions in this field has invariably provoked a ready response, and the discussions have brought out much valuable information regarding occupational diseases and their causes The work of the society has been actively supported by many general practitioners, a number of whom have lectured on its behalf, in addition to medical officers directly associated with industrial welfare work and medical officers of health The honorary secretary is Dr G Clark Trotter, and the secretary Mr J Mackenzie, 84, Kingsway, W C 2

A PHYSICAL TRAINING CENTRE

In its report and statement of accounts published this year the Royal Kensington Division of the British Red Cross Society gives a record of the progress made since October, 1919 The principal achievement of the division is the formation and maintenance of the physical training centre for civilians in succession to that started in 1919 for ex-service men under the auspices of the Ministry of Pensions The division has been entirely responsible for this centre, has worked for it, and raised the funds for its upkeep in the borough of Kensington alone The centre, which is in charge of two physicians, a fully trained sister, an almoner, and six full time and nine part-time massenrs, all fully qualified, places at the disposal of those who cannot afford the ordinary fees for private treatment the advantages of all kinds of physiotherapy, including massage, medical gymnastics, electrotherapy, and radiotherapy No patient is seen without an introduction from a medical practitioner, and doctors are requested not to send patients who can afford higher fees than the maximum charge of the clinic—that is, consultations 10s 6d, treatment 5s One great advantage of the centre is that it carries on its work during the evenings, thus enabling patients to take treatment without risk of loss of employment It also arranges, where necessary or advisable, for admission of patients to convalescent homes, for treatment and advice outside the scope of the clinic, for the provision of surgical appliances at reduced cost, and for x-ray examinations, either free or at nominal cost, at St Thomas's Hospital Some surgical instruments are made on the premises Additional work of the division is the training and examination of girl guides and members of girls' clubs, detailing of workers for first-aid duty at public exhibitions, hop-pickers' camps, etc., the formation of a depot lending medical requisites, and the establishment of a hostel for girls working in London A study of the tables of total patients treated and of the average cost of treatment during the period 1922-27 shows a continuous increase in the number of patients and decrease in the cost of treatment

THE Bradshaw Lecture before the Royal College of Surgeons of England will be delivered in the theatre of the College, Lincoln's Inn Fields, W C, by Mr C H Fagge, M S, F R C S, on Thursday, November 8th, at 5 p m The subject of the lecture will be "Axial rotation, purposeful and pathological"

SIR BERKELEY MOYNIHAN, Bt, P R C S, will deliver the Lloyd Roberts Lecture at the Manchester Royal Infirmary on Tuesday, October 23rd, at 4 15 p m, the subject he has chosen is "Some problems in gastric surgery"

VOTING papers in connexion with the election of two Direct Representatives upon the General Medical Council are being issued to day to all practitioners having registered addresses in England and Wales The joint election address of Dr J W Bone and Dr E K Le Fleming appeared in last week's Supplement, and a further list of their supporters is published this week

THE CAMPAIGN AGAINST TUBERCULOSIS

CONGRESS IN LONDON

THE fourteenth annual conference of the National Association for the Prevention of Tuberculosis took place, under the chairmanship of the Hon Sir ARTHUR STANLEY, on October 15th and 16th in the Great Hall of the British Medical Association House, Tavistock Square. The date of this event is usually midsummer, but this year it was put off until the autumn in order to coincide with the visit to London of between thirty and forty medical men representing the Canadian Tuberculosis Association, who have been undertaking a "scholarship tour" in Italy, France, and England. It cannot be said that, even with Canadian assistance, the discussions were well sustained, and the session arranged for the afternoon of the second day was abandoned.

Primitive Peoples and Tuberculosis

Dr R G FERGUSON, director of medical services of the Saskatchewan Antituberculosis League, gave an interesting lantern lecture on tuberculosis among the Indians of the great Canadian plains. He said that sporadic cases of tuberculosis among the plains Indians had been observed during the last seventy years, but not until 1884 did tuberculosis become so common as to assume the proportions of an epidemic. After the acute phase, which lasted less than two decades, the epidemic gradually subsided and the number of deaths slowly decreased, though even now, after forty-four years, the tuberculosis death rate among these Indians was about 800 per 100,000, or nearly twenty times that of the surrounding white population. There had been no loss of infectiveness following the epidemic, as shown by the fact that over 90 per cent of the school children reacted positively to tuberculin, nor had there been any apparent loss of virulence. He gave the results of a study of 147 families on the Qu'Appelle and File Hills reserves which had been traced through three generations. Only one family was found which had succumbed to tuberculosis alone, but five families had succumbed to tuberculosis alone except in the case of aged grandparents, and only three families had passed through the three generations without recorded deaths from this cause. Infusion of white blood by crossing was shown to have conferred increased resistance, resulting in decreased mortality, though not decreased morbidity.

Dr J J VASSIL, formerly director of health of French Equatorial Africa, sent a communication, which was read by his compatriot General JORDAN, on the conditions in French dependencies. He said that in the French colonies investigations during recent years, directed by Calmette, showed that in the oldest of such colonies there was to-day a tuberculosis mortality equal to that of France, colonies relatively new showed a steady growth of tuberculosis, while countries of the most recent French occupation still had regions and races almost immune. It was evident that when the primitive races, which had long been protected through isolation, came into contact with civilized races, infection occurred which assumed a severe and rapidly progressive form. It was not a question of greater or less susceptibility of race, no race escaped when submitted to contagion.

Professor LYLE CUMMINS, of the Welsh National School of Medicine, dealt with the position in Africa, where he had had two opportunities, separated by a long period of years, of studying the disease among the natives. During his earlier experience—about 1902—he went into the equatorial part of Africa and found primitive Africans who were, as far as he could ascertain, free from tuberculosis. Recently he had participated in an investigation among native miners of South Africa. A large number of South African natives now lived in territories where tuberculosis was endemic, and if the endemicity was of recent date there was great want of resistance to the disease. The spread of industry had altered the situation. The males left their native territories to go into industry on short contracts, there they worked with white miners, and infection spread among them. If they escaped infection their brief experience in the mining industry was beneficial to them, and they returned to their native settlements fit and

bettered in other ways, but some of them did develop tuberculosis, and others pneumonia and meningitis. Those who developed tuberculosis during the early months of their industrial experience got the disease in an exceedingly acute form. Professor Cummins reminded his audience of the imperial responsibility in respect of Africa, especially with regard to natives entering upon the physiological stress of industry. As for increasing the resistance to tuberculosis by means of inoculations, it could be said that, for natives from endemic areas, with a high percentage of positive tuberculin reactions, the applicability of BCG vaccine appeared to be restricted, where native labour was drawn from more primitive sources the opportunity of giving BCG vaccine a fair trial should not be missed.

Dr STEPHEN J MAHER (Now Havon, U.S.A.) produced evidence to show that in no form or another tuberculosis had always been a disease of the Indians of North America. Even in the wild these Indians had suffered from tuberculosis, and the doctrine that this was a curse which the white race had passed along to other races was false. He quoted from the collections of the Massachusetts Historical Society, among other sources, to show that before the English came among the Indians one of the two common diseases was consumption, the other being yellow fever. Dr A S LAMB, of the Provincial Department of Health, Victoria, B.C., described an investigation in British Columbia. Among the coast Indians active pulmonary tuberculosis affected a little over 5 per cent of the population, and other forms of tuberculosis, together with cases showing healed or non-active lesions, brought the proportion up to 10 per cent, probably ten times as great as the proportion among the whites. In the Indian reserves in the interior, where the climate was quite different from that of the coast, the proportion was practically the same as on the coast, though the relative proportion of non-pulmonary cases here was greater.

Anti-Tuberculosis Measures

The subject for discussion on the second day was "The principles underlying a scheme of anti-tuberculosis measures in any country." In the opening speech Sir ROBERT PHILIP, of the University of Edinburgh, said that the principles underlying an effective anti-tuberculosis campaign were simple and straightforward, yet their practical significance was far from being sufficiently apprehended. Many meritorious efforts against tuberculosis had suffered because of failure to give one or other principle its proper place, or from imperfect correlation of the several principles. These principles were (1) the morphological unity of tuberculosis in all its varying expression, (2) the essentially infective character of tuberculosis, necessitating that it be dealt with on the broad lines applied effectively to other infections, (3) the universality of infection (from this arose the recognition of the need for the tuberculosis dispensary, the tuberculosis officer, and the *caro communitate*), (4) the contraction of infection in childhood, implying the need for the scientific direction of preventive methods towards the infant, (5) the continuity of tuberculosis infection during life, and (6) the effect of environment on the course of the infective process, a study of which had led to the evolution of sanatorium methods of treatment. Had the lesson of the sanatorium been sufficiently applied in the preventive sphere? "If the tuberculosis officer and the family doctor," said Sir Robert Philip, "were constant in insistence on the re-creation of the home, and especially the nursery, on sanatorium lines, the danger of exposure to tuberculous infection and the consequences of such infection in childhood would be reduced to a minimum. When will education authorities face the facts and, instead of erecting special schools here and there for pronounced sufferers, boldly take the bull by the horns, and run all schools on those physiological lines which have proved themselves capable of placing developing life on a higher plane of existence?"

Dr J H HOLMROOK, a sanatorium officer of Hamilton, Canada, gave an account of the achievements in his area during the last twenty years, especially the establishment of a sanatorium which now served the whole province, and of a pre-ventorium for children. The result of the intensive work in Hamilton, carried out with the most hearty support of the community and the municipal authorities,

was that the death rate was now 49.5, which was lower than that of any other city on the American continent with 100,000 or more population.

Dr G. LISSANT COX, chief tuberculosis officer, Lancashire County Council, said that, reduced to the simplest terms, the principles which should govern anti tuberculosis measures were first, the application of preventive public health or social measures against this infective disease, secondly, the accurate diagnosis and treatment of the individual patient. The dispensary should be regarded as an organization, not a building, and the tuberculosis officer as its most important part. The Astor report recommended that the tuberculosis officer was to be in all cases a whole-time appointment, but at present there were nearly as many part-time tuberculosis workers (177) as whole-time (190), and few of these received the recommended salary, that equivalent to £500 pre-war. As to the tuberculosis dispensary area, here again, except in large county boroughs, like Birmingham, Sheffield, and Bradford, and a few counties, all with a high standard of anti tuberculosis work, the recommendation of the Astor report, that the dispensary area should contain not less than 250,000 population, had not been carried out. Notification in practice was not as perfect as it should be, and the speaker suggested that a Framingham experiment (that is, a systematic house-to-house search for tuberculosis, as made in one town in America) was called for in England, also periodic health examinations of the whole population, for until these were made a great number of very early cases would always go undiscovered. With regard to the institutional unit, the tuberculosis officer should be also in charge of a small hospital or of beds, and the medical superintendent of the larger institutions should be in charge of a small dispensary area. In this way there was no divorce between the dispensary and the institutional side of tuberculosis work. Sanatoriums should be kept small—not above 150 beds—and there should be a minimum for pulmonary tuberculosis of one adult sanatorium bed to 5,000 of the population, and one adult hospital bed to 6,000 of the population. Beds for children were additional—one to 24,000 for pulmonary cases, and one to 10,000 for non-pulmonary. "Let not the tuberculosis service be faint-hearted," said Dr Cox in conclusion. "Do not get side-tracked and run after every newly advertised panacea. Look at the splendid results in Sheffield and in Birmingham, where tuberculosis schemes exist under men of real ability. It is thro that the death rate has diminished by one-half and one-third in the last ten years. If you will give the tuberculosis service the means, this terrible scourge can be, and will be, conquered."

The remaining brief discussion was devoted chiefly to the recounting of administrative experiences, mostly having to do with housing in the localities of the speakers. The work in this direction at Middlesbrough and other places was described. As Sir ARTHUR STANLEY said at the close, every discussion of this kind in his experience had come back to the question of proper housing provision and the elimination of overcrowding. Sir JOHN ROBERTSON (M.O.H., Birmingham) warmly praised Sir Robert Philip's contribution, which he thought should be printed, perhaps in a rather more popular form, for the widest possible distribution. A Shore-ditch borough councillor said that the value of the new housing schemes was largely nullified by the increased cost to the wage-earner of getting to and from his work, and he begged that representations might be made to the Minister of Health with a view to some arrangement which could ease the burden. Dr J. H. ELLIOTT, President of the Canadian Tuberculosis Association, commented upon the absence of all reference to milk to stamp out this form of malady. He also emphasized the importance of medical inspection in schools with a view to the detection of early tuberculosis. Sir ROBERT PHILIP, closing the discussion, said that the whole purpose of his own contribution had been to point to scientific and therefore practical means of controlling and eradicating the disease. The work must proceed along biological lines, otherwise attempts at prevention would be a waste of time. He was of opinion that there should be no attempt at this stage to press for universal examination in this country, which he thought would be premature.

DINNER TO CANADIAN AND AMERICAN GUESTS

On October 16th the Joint Tuberculosis Council arranged for a dinner to be held at Verrev's Restaurant, at which over a hundred representative British tuberculosis workers acted as hosts to about forty of their colleagues from Canada and the United States. Sir HENRY GAUVAIN, who presided, was supported by Sir George Newman, Sir Robert Philip, Sir St. Clair Thomson, Professor Kenwood, and Sir Oscar Warburg, L.C.C. The chairman announced that, in response to a loyal message to the King, he had received a reply as follows: "The King has received with much pleasure the message of greeting which you have addressed to His Majesty on behalf of all present at your dinner to night, and thanks them for their loyal assurance. The King is glad to hear of the welcome accorded by the members of the medical profession to their colleagues across the Atlantic who are visiting this country for the purpose of attending the Congress of the National Association for the Prevention of Tuberculosis. His Majesty wishes you all God speed in your efforts to combat this scourge to the health and wellbeing of the community."

Proposing the toast of "The Guests," Sir HENRY GAUVAIN voiced the warm welcome which British medical practitioners engaged in the campaign against tuberculosis were glad to extend to their colleagues from the other side of the Atlantic, and commented on the great privilege which was theirs in entertaining representatives of a Dominion which had played such a valued part in the late war. He referred to the great service rendered by the Sun Life Insurance Company of Canada in making it possible for Canadian delegates to visit Europe, and expressed the hope that this meritorious act might receive the very favourable attention of British insurance offices. The toast was supported by Sir Robert Philip in a warm personal tribute, by Sir Oscar Warburg, who recalled the many joint ventures of Canada and Great Britain, by Dr Lissant Cox, chief tuberculosis officer for Lancashire, and by Dr C. O. Hawthorne, who voiced the greetings of the British Medical Association, and made mention of its coming visit to Canada two years hence. Dr Marcus Paterson, Dr Kelynnack, Professor Lyle Cummins, and Dr Jane Walker also spoke in support of this toast. Dr R. E. Wodehouse of Ottawa, secretary of the Canadian Tuberculosis Association, replied to the toast and emphasized the importance of the general practitioner in dealing with tuberculosis, especially when the battle had to be fought out in the home. He mentioned that the Sun Life Insurance Company had been in the habit of contributing annually and generously to the Canadian Medical Association, the donations rendered it possible to provide one- or two-day courses for practitioners in remote country areas. Dr Stuart Pritchard, who also responded, said that the time had come for the English speaking peoples to co-operate more closely. The toast of "The Hosts" was proposed by Dr W. J. DONNIE of Weston, Ontario, in a clever, witty speech. He remarked that tuberculosis recognized no international boundaries, and he hoped that very many of the hosts of that evening would be able to visit Canada in the future, when they would receive a very warm welcome. Replying to the toast, Sir GEORGE NEWMAN congratulated the Canadians on continuing to be pioneer adventurers of the British Empire. He believed that in no part of the world was the prospect of defeating tuberculosis better than in Canada, where an increasing population would find ample space for expansion for many years to come. Dr Ernest Ward, honorary secretary of the Joint Tuberculosis Council, also replied to the toast. Dr J. H. ELLIOTT of Toronto, in proposing the toast of increased prosperity to the Sun Life Insurance Company of Canada, made mention of the long history of this institution, and gave illustrations of its great value as a national organization, especially with regard to the prevention of tuberculosis and the improvement in the mortality figures. Mr T. B. MACAULAY, president of the company, in his reply, expounded the high ideals with regard to the promotion of health which inspired the various steps taken. He gave details of difficulties which had been overcome, and expressed confident hope with regard to increased activities in the future.

INTERNATIONAL SOCIETY OF MEDICAL HYDROLOGY

ANNUAL MEETING IN ENGLAND

THE International Society of Medical Hydrology held its annual congress in England from October 9th to 17th. The first three days were spent in London in a series of discussions and other events, after which the members visited Harrogate, Buxton, Droitwich, and Bath. At least nine European countries and the United States were represented, and French and German were heard in the discussions more frequently than English. A noteworthy visitor was Professor Umberto Gabbi of Parma University, who was president of the gathering when it met last year in Italy, and who came by air direct from a congress at Turin, leaving again by air two days later to attend a congress in Rome. The president this year was Lord Dawson of Penn., and the vice-presidents were Dr. W. Edgecombe, Dr. C. W. Buckley, and Dr. Rupert Watkinson, of Harrogate, Buxton, and Bath respectively. The genius of the meeting was Dr. Portescue Fox, chairman of council, who combined with a talent for self-effacement a remarkable skill in handling an international occasion.

The proceedings began with a conversation at the Royal Society of Medicine on the evening of October 9th, by invitation of the Section of Balneology and Climatology. The guests were received by Lord Dawson, president of the Society, and Dr. G. L. Kerr Pringle, president of the Section, and a number of interesting exhibits were on view, lent by the Wellcome Historical Medical Museum. Lord Dawson, after extending a welcome to the visitors, spoke of the great industrial wastage caused by subacute or chronic rheumatism. Invalidity due to this cause in 1927 led to a loss in Great Britain of 5½ million working weeks. One of the subjects before the present conference, he said, was the extension of remedial measures to all classes of the community—making what had been the privilege of the few the right of the many—a task which needed an extended organization and the participation of the State. But valuable as spas might be, Lord Dawson continued, they would not alone suffice for the treatment of a disease so widespread among the workers. Treatment must be brought to these people in their cities, within reach of their homes and workplaces. City clinics were being established in various countries, one of them in London. Such clinics could not offer advantages comparable to those obtained in spas, with their environment and atmosphere, but if the spa was to fulfil its complete function its ambit must be widened. The new outlook which aimed at the preservation of health, and therefore the correction of physiological digressions before these became co-ordinated into ill health, had its effect on the spa. With the value now attached to fitness by the younger generation, there was not likely to be in the future the same proportion of the obese, the plethoric, the bronchitic, the gouty, and the rheumatic. These conditions would not be allowed to arise. Health values were truer than formerly. To be fat, inert, and gouty was no longer regarded as inevitable, still less as acceptable, and might come to be regarded as "bad form." This led one to hope that the spas, in addition to treating those suffering from various disabilities, might be able to make provision for a still larger number of people who, though guilty of various divergences from physiological correctitude, were still able-bodied and could enjoy their holidays while undergoing a pleasant discipline. By the co-operation of the spa municipalities and the medical profession appropriate provision might be made for these "threshold" cases.

The first official meeting was held at the University of London, when Sir HOLBERT WARING, representing the Vice-Chancellor, extended a welcome to the visitors, and mentioned that when London had its properly established post-graduate school of medicine, which he hoped would not be long delayed, one of the departments would be medical hydrology. Dr. ALISON GLOVER brought greetings from the Minister of Health, who, he said, recognizing that the expansion of the provision for physical methods of treatment was a matter of urgent national importance, was eager to learn all that he could of the methods pursued in

this country and abroad. In no branch of medicine was the international spirit more necessary than in hydrology, and such a society combated that national bias which early found expression in the preference of Naaman for Abana and Pharpar, rivers of Damascus.

Spas and Insured Persons

The first discussion was on the health resort and national health insurance. Dr. C. W. BUCKLEY (Buxton), in opening, said that the organization of spas to meet the needs of wage-earners and their dependants might proceed on several different lines. There might be State organization and control of several small spas whose resources were at present inadequately developed, so that they were made available principally for those who required assistance to enable them to undertake treatment, this would entail subsidies from the State. Again, spa hospitals might be utilized and further developed, especially for the more serious cases, this need not destroy their voluntary character, but their funds could be assisted by payments from approved societies. Finally, there might be in all spas certain clinics organized by the medical profession or the municipality, or serving as a department of the spa hospital, to provide medical attendance, baths, and physical treatment, and research facilities. Whatever plan was adopted it was essential to have a central bureau to organize and co-ordinate the whole scheme, and this must obviously be the function of the State. He added that it was essential that the medical profession in the spas should so organize itself as to guide and influence any schemes of this nature, and the newly formed Spa Practitioners' Group of the British Medical Association was an ideal means to this end.

An interesting account of German spas in the service of social welfare was given by Dr. MAX HIRSCH (Charlottenburg). State-controlled social insurance in Germany, he said, dated from the early eighties, by 1914 one-third of the German people were socially insured, and the proportion now was one half. Spa treatment could not be demanded as a right by those in insurance, but it might be given, and its advantages were early recognized by those in administration because it shortened the period of illness and saved sick pay. The practice of sending insured patients to spas was constantly increasing. It was the custom for the sickness insurance offices to enter into agreements with particular watering places for accommodation and treatment for their members at reduced cost, in a few cases watering places had been purchased by these offices. The control of insured persons at spas was quite practicable, even when they were lodged in private houses. The average time of a bath cure for a patient in invalidity insurance—that is, a patient convalescent after sickness or suffering from debility—was thirty-one days. Patients were thoroughly examined by a doctor before being sent to a spa, and the choice of spa was made as a result of that examination. The results with insured patients were better than those with non insured, because the former took their cure more seriously, without unduly engaging in diversions.

The experience of one German State spa, Bad Elster, in Saxony, was related by its Kim-Direktor Dr. Etienne, who said that a large number of homes for different classes of patients had been established there, including one home, with 160 beds, by one of the large trade unions. Every visitor paid a "cure tax" entitling him to the use of the waters and to certain social amenities. An assisted or "public" patient generally had a reduction of 20 per cent on his "cure tax," as well as on the price of his baths, and the spa physicians also reduced their fees to such patients. Dr. Etienne gave some figures for German spas showing the annual number of visitors (presumably in 1927) and the number sent and paid for by public organizations.

	Total Visitors	Public Visitors
Badenweiler	12,249	1,032
Bad Elster	14,501	3,541
Harzburg	17,130	860
Landeck	11,039	4,046
Oeynhausen	20,252	3,601
Nauborn	31,284	11,758
Salzungen	25,570	3,485
Wiesbaden	46,060	5,597

In addition, at each spa there were some hundreds—at Nauheim and Oeynhausen some thousands—of single cases in which reductions were granted. The criticism was made by certain spa administrations that the presence of "social" patients affected the atmosphere of the resort, and made the visits of wealthy patients less frequent. But many of these poorer visitors belonged to the cultured classes, having been brought down by economic misfortune, and even those of rougher manners responded to the refinements of the spa. One point of view put forward by an American visitor to Bad Hister was, "One's own cure is made sweeter by the sight of many of these unfortunates creeping back to health and strength."

An account of recent legislation affecting French spas was given by Dr DURAND FARDOL. In the decrees and regulations issued in France from time to time regarding mineral springs, increasing emphasis had been laid on the principle that the public interest or the interest of the patients using the waters must have precedence over the rights of the owner. An Act of 1910 authorized the levy of special taxes in recognized resorts, the revenue so derived being intended to provide the spas with the financial resources for their development and equipment. Professor GAUAT, speaking of the position in Italy, said that the spas in that country, which numbered 700, belonged to the State, to municipal bodies, societies, and private persons. Each spa had a "cure committee," on which there had to be at least one medical man, and at the Ministry of Finance there was a central organization which supervised these local committees. Facilities were granted by the Government to poor persons who were recommended for treatment, and by arrangement with trade unions workmen were able to secure such treatment. Every user of the baths had to pay a "cure tax."

Dr GUNNAR KÄHLMEIER said that in Sweden there was no State health insurance against sickness, but 13 per cent of the population belonged to private clubs which gave sick pay, though they did not defray expenses incurred at hospitals or spas. Treatment at spas could, however, be obtained at a reduced payment—or in some cases without cost—by those who, becoming incapacitated by disease, were entitled to any form of State pension. The spas of Czechoslovakia were described by Dr L. SCHMIDT of Pistony as health and treatment resorts for the whole population. His country had decided to erect a balneological institute to encourage the improvement of hygienic and public health conditions at spas, and scientific and experimental research in connexion therewith. Finally, Dr VICOI told of what was being done in Rumania, where there were 25 principal health resorts and 56 smaller ones. The control of all watering places was exercised by the Ministry of Health, and each of the resorts had a medical council. The principal insurance corporation in Rumania, in connexion with which three and a half million medical and surgical consultations took place in 1927, had important installations in three spas, and made arrangements last year whereby more than 3,000 patients were sent to these resorts.

After Dr JOHN MURRAY (Llandrindod Wells) had spoken of the great burden imposed upon British industry by rheumatic invalidity, and the need for impressing on the public, local authorities, and the Government the important place which spas ought to occupy in the treatment of chronic disease, the discussion was closed by Dr KERR PRINGLE (Harrogate), who urged that the State should safeguard British spas as national properties. Some of the spas were suffering from the growth of manufacturing districts in their vicinity, the development of locomotion brought to them people who used them only as sleeping quarters or places of excursion, and had no real interest in them as spas. The State, having declared all mineral springs national property, could lease them to local authorities at a low rental, and allow the authorities, in return for good management, to impose a "cure tax." The State should also put a ring fence around the spas, thus creating a health centre where there would be no noxious trades, and no pollution of atmosphere, where noise would be reduced to the minimum, and town planning conditions enforced.

The Humoral Factor in Disease

The second medical discussion was on the subject of "neo-hippocratism," or "the humoral factor in disease." This took place at Burlington House under the presidency of Lord DANSON. In an opening paper Dr M. B. RAY (London) traced the doctrine of the four cardinal humours (blood, phlegm, and yellow and black bile) from Hippocrates and Galen down to the middle of the seventeenth century, when the final blow was given to its general credence by the tardy recognition of the work of Harvey. Sydenham revived the Hippocratic doctrine of observation and experience as the main essentials in the practice of medicine. The seventeenth and eighteenth centuries were marked, said Dr RAY, by a continual striving after the formulation of "medical systems," and from this there followed a period when clinical medicine was based principally on pathological findings, which exhibited only the static aspect of disease. The brilliant work of Virchow and Cohnheim, who revolutionized current ideas regarding inflammation, and the later researches on the internal secretions and in biochemistry had shown that many so-called organic diseases, manifesting local anatomical pathological changes, were only secondary results of metabolic disturbances or blood disorders. To differentiate the new ideas on etiology from the old, the speaker suggested the designation "neo-humoralism," which implied the concept of disease as primarily due to changes in body fluids, in respect to their excess, deficiency, retention of products of metabolism, and so on.

Dr PAUL FÉREYROLLES (La Bourboule, France) spoke of the value of waters in ameliorating, transforming, and dissipating humoral disorders. If the mode of action of waters were better known the origins of these morbid states would be better known also. The blood, like a medicinal water, was a complex solution of electrolytes, and it was reasonable to suppose that changes took place when the blood was deficient in certain elements. He argued for the notion of a *lipoidal disequilibrium* as a factor in diathesis, which might be corrected by waters.

Dr A. P. CAWADIAS (London) described the present period in medicine as that of "neo-hippocratism." The principles of the organic localization of disease which had attracted medical science during the last hundred years were being abandoned, and a much wider and more comprehensive conception derived from the doctrine of the ancient Greek physicians was making its appearance. The body was a unit, and could not be considered as a collection of smaller units, organs, cells, or molecules, all these were correlated, and formed on integrating whole. It was the whole organism which became diseased, there were no diseases of organs, of cells, or of tissues. Disease was a disharmony of life, a defect of adaptation. The neo-hippocratic theory had completely changed the conception of diagnosis, which now became a triple operation, consisting of disease diagnosis, functional "personality" diagnosis (the answer to the question to what extent the individual was injured by his complaint), and "diagnosis of the etiological constellation." With the introduction into medicine of this new conception, the role of specialties in practice was being modified. Specialization in technique was useful, but in diagnosis impossible. The surgical specialties would remain, but the more recent splitting of internal medicine would be abolished, as it was being abolished in most Continental schools. In treatment also the new theory had opened wider horizons. Dr Cawadias declared that a new period was opening for medical science. A new medical peak was being approached, and once more, as in Sydenham's days, by a return towards Greek sources. The neo-hippocratic theory was one of those great synthetic conceptions so important for the progress of human thought, and although no Hippocrates had yet appeared to give that theory its precise formulation, much had been already accomplished, even with the vague and fragmentary notions we possessed. Professor E. H. KETTLER (St Bortholomew's) said that the more one studied microbial diseases the more one was impressed by the fact that each particular type or group of organisms appeared to have an affinity for different types of tissues. The clear-cut localization of microbial

lesions was most remarkable. It should be possible to adopt a much more rational method of treatment of infectious diseases than the profession had been in the habit of employing. For the last thirty years or more infectious diseases had been largely attributed to the circulation of the blood, but the blood could not give a true indication of what was actually taking place in the body. To have regard to the blood alone was like making an attack with the blunderbuss instead of the rapier. Many blood changes in disease were purely secondary, not really vital changes. The diagnosis of enteric fever, for example, rested upon the demonstration of specific agglutinins in the circulating blood, but those agglutinins had very little relation to the actual process of infection, and their persistence was variable in different individuals. The question of infection or non-infection depended on the tissues entirely, not on the circulating plasma. The essential part of any infection was the direct combination between the tissues of the body and the infective organism, and inasmuch as each group of organisms affected a particular group or type of tissues it should be possible, by modifying the condition of the specific tissues involved, to modify considerably the progress of the infection in the patient. He did not think there was evidence that any specific treatment would alter this condition of the cells permanently, or even sufficiently to make infection impossible, but the best results were to be hoped for by such regime and treatment as would influence the body tissues.

The discussion of so large a theme was hampered by lack of time, and succeeding speakers were compelled to compress their remarks very closely. Dr. SARGENTO (Portugal) related how by studying the action of the Vidago waters in his country in certain affections he had found abundant confirmation of the importance of the humoral factor in disease. He held that the doctrine which saw the origin of certain diseases in the body fluids must be regarded as a necessary conception, especially in experimental and physico-chemical medicine. Dr. E. P. POULTON (London) described some recent biochemical investigations carried out with Dr. Obermer in cases of chronic rheumatic disease; he exhibited in diurnal curves the urinary picture in such cases, and pointed out its significance in various respects. He suggested that differences in biochemical make-up appeared sometimes to be congenital and sometimes acquired—for example, the allergic state—and that the effects of heredity and environment (including disease) could not at present be distinguished. Dr. MAX HINSON (Charlottenburg) said that although medical opinion and practice were now swinging back from the consideration of the disease itself to the Hippocratic method of making the sick person the focus of attention, the study given to diseases had not been without its fruit, and the return to Hippocratic theory and practice was made with much better understanding in consequence.

International Standards

At another session during the London part of the meeting an international standard of measurement in the analysis of waters was considered. Last year when the Society held its congress in Rome a committee was appointed to consider this subject and make recommendations. The proposals, which were endorsed by the council, were now presented by Dr. Judd Lewis and agreed to unanimously. It had previously been agreed that the analysis of a water should always be expressed in terms of ions, whether its interpretation in other terms was given or not, that the quantities of ions, also "salines" when stated, should be given to one decimal place only, also that the specific gravity should be determined by comparison with distilled water at the same temperature. It was now agreed to add to the proposed tables of analysis an extra column in which the ions or salines were given in terms of their "multi-normality"—that is, the number of times the molecular weight of the ion in milligrams is contained in a litre of water. It was further agreed, in order to avoid the use of cumbersome decimals, and to bring the analytical data into line with the customary dose of waters as nearly as possible, to adopt as an international standard measurement the expression of analytical data for the constituents of waters in terms of

parts per 100,000. The tables which the council of the Society will print in futuro will show for each ion or saline constituent of the water its concentration in parts per 100,000, its concentration in terms customary in the country where the water originates, and the same in terms of "multi-normality." It was also agreed to form in each country a national committee to give effect to the International Society's proposal.

Other events of the meeting in London were receptions at the Royal College of Physicians and at the Wellcome Historical Museum. At Harrogate the members were the guests at dinner on successive evenings of the mayor and corporation and of the Harrogate Medical Society. Here a discussion took place on the treatment of children by waters and baths, and demonstrations of rheumatic cases were given at the Royal Bath Hospital. At Buxton hospitality was similarly extended by the municipality and the local profession. A general discussion took place here on rheumatism as a national problem. Droitwich Spa was visited on the way to Bath, and here again the members were welcomed municipally and by their medical colleagues, and were entertained to luncheon by the Corbett trustees in the Salters' Hall. We hope to publish a more detailed account in the next issue.

HEALTH OF THE ROYAL AIR FORCE

REPORT FOR 1927

THE medical aspects of problems associated with the efficiency of industrial workers are now recognized as being of national importance, and in this connexion the researches into flying efficiency carried out by the Medical Department of the Royal Air Force have considerable interest. One of the problems recently investigated is that of fatigue caused by flying, and an account of this appears in the Report on the Health of the Royal Air Force for 1927.

"Fatigue" was estimated by physiological tests for respiratory and circulatory efficiency, and general nervous stability, and by a system of marking an "efficiency index" was obtained. The results showed that individuals who had been specially selected, by passing the medical examination for flying passenger-carrying aeroplanes, could fly for long periods without showing fatigue. When a pilot had flown over 100 hours in any one month there was, generally speaking, no appreciable amount of fatigue noted, although certain signs of the onset of stress were observed. In one instance, however, the marks obtained in the efficiency index fell to a very appreciable degree. The figures show that re-examination of aeroplane pilots is of value in enabling conditions predisposing to flying fatigue to be discovered and rectified early.

Medical fitness and accidents were also investigated. The method adopted was to study all accidents due to fault on the part of the pilot, and to calculate the physical efficiency index and also the index of visual judgement. The report gives a summary of the results which indicates that lack of physical efficiency (including visual efficiency) cannot be regarded as a factor in the causation of accidents.

In view of the observations made by Muscio² on industrial workers, where a definite increase in accidents occurred with the onset of fatigue, the method of the Royal Air Force in selecting individuals capable of enduring fatigue, and of applying routine tests to discover the early signs of stress, may be of interest.

It is claimed that the record of Imperial Airways during the three years 1925 to 1927 (approximately 2,400,000 miles flown and 54,000 passengers carried without a serious accident) must be attributed, in part at least, to the careful medical selection and periodic re-examination of the pilots of aircraft carrying civilian passengers.

Those who are concerned about the distressing effects of street noises on sensitive persons will be interested to learn that attempts have been made by the Medical

 - Lectures on Industrial Psychology

Department of the Royal Air Force to provide protection for pilots against the deafening noises of aeroplane engines. A simple and effective ear defender has been devised which cuts off the painful and fatiguing vibrations, while enabling the pilot to hear the wireless telephone and other sounds perfectly.

A synopsis of the Royal Air Force medical officers' course of instruction is given in the report. Such subjects as applied pathology, hygiene, tropical medicine, and hospital routine are taught by scientific experts of the highest repute. Inspection of the syllabus given suggests that the training and experience obtained in the Air Force should result in an excellent type of medical officer.

The health of the Royal Air Force at home and abroad has been good, and the figures for sickness, deaths, and invaliding incidence during 1927 compare favourably with those of the previous year. Sickness figures are shown for the fleet air arm this year for the first time. Life appears to be healthy in the Royal Air Force, and although the majority of the men are serving in Iraq, India, Egypt, Palestine, Aden, and Malta, only ten cases of illness due to the effect of heat are recorded. Accidents caused by athletics and motor cycling while off duty are among the chief causes of injury. Flying accidents only amount to 6.4 per cent of all injuries. This figure is the lowest since 1923, and, taking into consideration the number of hours flown per accident, the casualty risk is the lowest ever recorded.

In conclusion, it may be pointed out that the annual reports of the health of the Royal Air Force are a mine of information for those interested in the physiological standards of normal healthy adults. The report contains thirty-one tables of statistics of various sorts, and in Table 24 are given the average results of pulse rates, blood pressure, etc., of 1,827 serving officers of the flying branch and 22 airman pilots. It is worthy of special mention that, although some 20,000 records have been obtained since these physiological tests were first standardized during the war (the pilots selected being chosen by the executive branch of the service) there has been no appreciable variation in the pulse rates and blood pressures of officers who were fit for flying duties.

OLYMPIA MOTOR SHOW.

MORE POINTS FOR MEDICAL MEN

[FROM OUR MOTORING CORRESPONDENT.]

THE 1928 Olympia Show, which closes to-day (October 20th), has continued to draw the general public. At times, indeed, the huge building has been uncomfortably overcrowded, rendering close inspection of any of the more popular cars practically impossible. There has been some talk of changing the exhibition from an annual to a biennial event owing to the heavy financial load it thrusts on exhibitors. Certainly, if it is to continue yearly, and exhibitors are to secure a reasonable return for their outlay, this question of overcrowding is one that will have to be considered seriously by the Society of Motor Manufacturers and Traders, responsible for the organization of the exhibition. Lieut Colonel J. T. C. Moore-Brabazon, M.P., broadcasting his impressions of the show from 2LO, touched on one of its weak spots when he said that much of the overcrowding was due to the large number of motor agents and their representatives who hang about all day round the popular car stands in the hope of picking up a stray order or two. Many will agree that this competition for orders is defeating its own ends. Visitors to the show, finding themselves unable to get near the chassis or car they wish to examine, but importuned instead by too enterprising agents, are inclined to go away in disgust. The Olympia Show should be what its title calls it—an exhibition rather than a mart, and some action to prevent overcrowding, particularly by touting agents, is to be desired.

A Technical Survey

An interesting summary of the tendencies in motor car design and construction as shown by the 1929 models has been prepared by the Autocar, which largely bears out

the views expressed in the *British Medical Journal* of October 6th. Thus it shows that of the British and foreign cars at present on the market in this country the majority of makes are fitted with six-cylinder engines, these now forming 49.6 per cent of the total as against 34.6 per cent for the four-cylinder type, the balance being divided between cars with two, eight, and twelve cylinders. Ignition is still mainly by magneto, but is closely followed by the coil and distributor variety. Cone clutches are now found only on 5.4 per cent of cars, as against over 71 per cent with the disc form, gearboxes providing four speeds are used to the extent of nearly 59 per cent of cases, those with three speeds only forming about 41 per cent of the total. American influence is seen in the change speed lever position, this being central in 67 per cent of cars, lateral in only 33 per cent. The spiral form is the predominant type of bevel gears employed for driving the back axle, being found in 89 per cent of cars, worm-drive is found in 9 per cent, and straight bevels and miscellaneous gears in the remainder. Finally, it is interesting to learn that wire wheels are now used on 47 per cent, or nearly one-half, of the different makes of cars, disc wheels, once so popular, on less than 13 per cent.

Leaving Cars Unattended A Missing Detail

British car manufacturers might with advantage copy certain of their American competitors in providing some form of lock for the steering gear or change-speed control to prevent the stealing of unattended cars. Many doctors drive themselves, and therefore have often to leave their cars unattended. The doors of most covered cars are now fitted with locks which are good so far as they go, but what is required is some simple yet effective device that will prevent open cars from being tampered with and driven off by thieves. Many doctors would welcome such a safety device, even at the cost of sacrificing some of the accessory conveniences now included in the specification of the generality of cars.

More Six-cylinder Cars

There are so many interesting cars at the show that it is impossible in the space available to mention them all. One may, however, refer briefly to some of the better known. Thus, A.C. Cars, Ltd., are now concentrating attention on vehicles with six-cylinder engines of respectively 16/40 h.p. and 16/56-h.p., the last-mentioned being built in both short and long chassis forms. The cars exhibited include one with a striking "sunshine" saloon body. Bean Cars, Ltd., are offering 14/35-h.p. and 14/70-h.p. four-cylinder cars, identical in chassis design except that the higher-powered vehicle is fitted with what may be regarded as a "sports" engine. All the Bean cars are now provided with unsplinterable glass windows, and Dewandre servo-operated brakes. The cars made by Bentley Motors, Ltd., are admittedly among the higher priced ones, but from the constructional point of view they occupy a very high position in the motor industry. Brocklebank and Richards, Ltd., are displaying the Brocklebank 14.9 h.p. six-cylinder chassis containing many details of interest, an attractive complete car being a four-door saloon covered with black fabric and upholstered in green leather.

American and Canadian Examples

Among the better known American and Canadian cars are the Buicks, the lowest-powered model of which, the 25/75-h.p., has undergone considerable change in design, detail, and coachwork. The engine has a larger bore, improved cam shaft, and valve mechanism, and quieter starting gears. Many improvements in the bodywork add both to comfort and appearance, and all the bright external parts are now chromium plated. The La Salle and Cadillac cars are still fitted with V-type eight-cylinder engines, but several noteworthy modifications have been made. The most interesting development is the new "synero-mesh" silent change-speed gear, to which reference was made in a preceding article. Roller bearings are used on all the brake cross shafts in place of bronze bushes. The wind-screens and windows of both cars are now of safety glass. Another well known American production now very popular

in this country is the Chrysler. The present range includes a new model known as the "65," the six-cylinder engine of which is rated at 23.5-h.p. Among the complete Chrysler cars on view one that is attracting attention is a business coupe listed at £392. For the coming season it has not been found necessary to make any change, either in the design or price of the Essex six-cylinder car, the model known as the 4/5 seated coach remaining at £250.

Clyno, Crossley, and Daimler

The Clyno Company are concentrating on the 9-h.p. and 12/35-h.p. four-cylinder models introduced last year. Improvements in detail only are evident, and both chassis are being supplied with other standard or *de luxe* equipment. There are four models of the 9-h.p. cars, ranging in price from £112 10s. for the four-seater with improved fabric bodywork, to £160 for a two-door *de luxe* saloon. With the 12/35-h.p. chassis there are three models of standard and four *de luxe* cars. In the former prices range from £157 10s. to £200 for the four-door saloon, while in the latter there is a four-door Olympia saloon at £275. Of the three types of six-cylinder cars now built by Crossley Motors, Ltd., the one most likely to appeal to medical men is the 15.7-h.p. model, which, as a saloon, is priced at £550 or £575, according to the finish. The details of the chassis have undergone little or no alteration since last year, the 1928 cars having given every satisfaction in users' hands. The Daimler Company, Ltd., the pioneers of cars fitted with sleeve-valve engines, have hitherto made highly priced *de luxe* cars. For 1929, however, they have introduced a 16/65-h.p. six-cylinder car with fabric saloon body at only £595.

An Italian Representative

An Italian car with many admirers and users in this country is the Fiat, the range of which includes 9-h.p., 12-h.p., 26.8-h.p., and 17/50-h.p. models, the first two having four-cylinder and the others six-cylinder engines. The 9-h.p. and the 12-h.p. models are adequate to the requirements of most medical practitioners. In the smaller type a fixed-head coupe at £235 attracts attention. For those requiring more power and a roomier vehicle the 12-h.p. four-door saloon is worthy of inspection. This model has a side-controlled four-speed gearbox and a wheel base of just over 9 ft.

Fast Car Specialists

Lea and Francis, Ltd., who have built up a reputation for speedy cars with highly efficient four- and six-cylinder engines, are showing, among other models, an attractive 12/40-h.p. fabric saloon at £440 and a coupe at £400. The Rhode Motor Company, Ltd., are concentrating on a single type of 11-h.p. Rhode Hawk chassis. This has a wheel base of 10 ft. 4 in., enabling a roomy saloon body to be fitted. Two other manufacturers specializing in speedy vehicles are Lagonda, Ltd., who are building 12.7-h.p. four-cylinder and 17.7-h.p. and 19.2-h.p. chassis, fitted with both open and closed bodies, and the M.G. Car Company, whose productions range from an 8-h.p. four-cylinder "sports" two-seater to a 17.9-h.p. six-cylinder four-seater "salonette."

A Novel "Sunshine" Saloon

The cars built by Singer and Co., Ltd., are among the most popular in this country. The firm are continuing the 8-h.p. Junior and 12-h.p. Senior four-cylinder models with certain improvements in the details, easily operated "sunshine" saloons being now available on both chassis. The 16-h.p. six-cylinder Singer has been considerably improved, and in view of the increasing popularity of light "sixes" and the relatively low price of the Singer, it merits the attention of doctors. Leyland Motors Ltd. continue steadily to improve the outward appearance of their novel but reliable 10-h.p. Trojan car. It is the only vehicle in the exhibition with a two-stroke engine and, in addition to open cars, is now being supplied with saloon bodies of either the permanently covered or the "sunshine" type.

Rovers and Sunbeams

Improvements in the outward appearance and internal furnishing are also the chief alterations in the cars of the Rover Company, Ltd. Only two types of chassis are being made—the 10/25-h.p. four-cylinder and the 16-h.p. six-

cylinder. The "Nippy-Ten" range includes a Weymann saloon with leather or cloth upholstery at £250, the prices of the "six" ranging from £395 to £460. The Sunbeam Motor Company, Ltd., is another firm which has not found it necessary to change the mechanical details of its cars. Four sizes of six-cylinder cars are being made in addition to a 35-h.p. "straight eight," the smallest "six" being of 16.9-h.p. New designs in bodywork are, however, apparent, and one or more of these will doubtless appeal to doctors. Sunbeams are not, of course, cheap cars, but have an excellent reputation for reliability and efficiency.

Stars and Swifts

The Star Engineering Company, Ltd., is concentrating on two sizes of six-cylinder chassis—20/60-h.p. and 18/50-h.p. The Star Company is one of the oldest in the industry, but is keeping well abreast with modern ideas of design and construction. Its cars are maintaining their long-held reputation for reliability and durability. For 1929 Swift of Coventry, Ltd., are mainly devoting attention to the 10-h.p. Swift vehicles, an important alteration in which is the adoption of a four-speed gearbox in place of the three-speed one formerly employed. The range of bodies includes a neat two-three-seater coupe and an improved "sunshine" saloon.

Clement Talbot, Ltd., are confining attention to a single Talbot six-cylinder model of 14/45-h.p., which has proved so satisfactory that little or no change has been made in the details since last year. The cars of the Triumph Cycle Company, Ltd., are notable more for quality than for low price. Their two models, of respectively 15-h.p. and 7-h.p., possess many features of merit. Wolseley Motors, Ltd., of which Mr. Morris, of Morris cars, is now the head, have some excellent cars at considerably reduced prices for the 1929 season. The Wolseley Company have a long-established reputation for reliability, and the 12/32-h.p. four-cylinder and 16/45-h.p. six-cylinder models are well worthy of consideration. Among the French cars popular in this country are those of Renault, Ltd. For 1929 the prices of some of the models have been reduced, the 9/15-h.p. and 14/45-h.p. saloons, both four-cylinder, being now respectively £182 and £269, while the 12.5-h.p. six-cylinder saloon has been reduced to £258.

Notable Motor Bodywork

The Annex to the Main Mall is, as usual, occupied by a display of motor bodies. This forms an exhibition of its own, and contains many pleasing examples of the coach-building craft. Most medical practitioners have perforce to be content with the standard form of bodywork supplied by the car manufacturers. Most of the latter are prepared, however, to supply chassis to motor users who prefer to have the bodywork built to their own requirements. Needless to say, this is generally a little more costly, but, to those who can afford the outlay, is compensated by the greater satisfaction.

It would occupy too much space to deal with each of the exhibits in the bodywork section, many of which, indeed, are too large and elaborate for doctors' use. The writer's attention was, however, attracted by a very smart fabric coupé body fitted to an Austin 16-h.p. six-cylinder chassis on the stand of Mann, Egerton and Co., Ltd. The two main seats are of the sliding bucket type, while behind them are two occasional tip-up seats. The car can thus be used as either a two or four-seater, while its range of usefulness is increased by a luggage boot at the rear and a "sunshine" roof, which enables it to be run either as an entirely closed or partially open car. Gordon England, Ltd., whose methods of body construction are special to themselves, also display some attractive bodies which will appeal to users of even popular-priced cars. Thus, on the stand are a special saloon body for the Austin "seven" and a very attractive design of five-seater two-door coupé on a Morris 17.9-h.p. "six" chassis.

A Look Round the Galleries

So many and various accessories are now manufactured for the convenience of motorists that a walk round the galleries at Olympia is a revelation of the progress of motoring. Space will not allow reference to more than a few of the many useful articles on view.

A winter driving convenience now widely used is a muff for the radiator. This is designed to prevent rapid cooling of the water in cars that have to be left standing for some time, and thus to prevent difficulties in re-starting the engine. These muffs are now available for most makes of cars, and a big range of them is shown amidst a wide selection of other accessories on the stand of Gamages, Ltd. When using radiator muffs one must get into the habit of dropping the flap when leaving the car and of raising it on re-starting, otherwise, when driving with a flap accidentally left down, there is a risk of overheating the engine and of boiling the water away. Some useful rugs for winter use are also to be seen on the Gamage stand. Dunhills, Ltd., is another firm displaying a variety of useful accessories, including radiator muffs, safety garage-heating lamps, and a spotlight with a special anti-fog disc, handy when fog or mist are encountered during night driving. The regular running of motor engines depends very largely on the sparking plugs used, the choice of these being another matter in which one may be penny wise and pound foolish. Reliable plugs are now made by quite a number of firms, among the better known being the Lodge, K.L.G., and Champiou. All of these firms have a range of patterns designed to give satisfactory firing in different makes of engine. In addition to one or two new models specially intended for use in high-compression engines (in which considerable temperatures are generated) Lodge Plugs, Ltd., have recently improved the brass terminal so that the Lodge weatherproof terminal can be used on any model of the firm's plugs.

Wind-screen wipers are another modern convenience of all weather driving. Any one of the many varieties can readily be fitted to a car if it is not already so equipped. Among the devices are the Vokes and the Klaxon, it being claimed for the latter that its action is unaccompanied by the usual clicking noise. Doctors who look after the oiling and adjustment of their own cars will be interested in the improved forms of pressure grease guns shown by the Tecalemit Company, Benton and Stone, Ltd., and other firms. The last-mentioned firm has brought out a new form of gun known as the Eacots "Autolub," suitable for oil or grease. By means of this it is claimed that the task of oiling and greasing a car can be comfortably and efficiently performed by one hand. Among the interesting exhibits of Jenks Bros., Ltd., is the Stevenson fixed-to-the-car jacking system, an arrangement which reduces the delay when punctures are encountered and tyres have to be changed. The device also facilitates the recommended practice of occasionally changing over front and back tyres, as by the Stevenson jack the two wheels on each side of the car can be simultaneously raised from the ground.

Another Anti-dazzle Device

In the first article of this series (October 6th) the view was expressed that the real solution of the headlight dazzle problem had yet to be found. While this is true, examination of the many devices shown in the galleries indicates that excellent progress towards a solution is being made. Lucas's new "dip and switch" device has already been mentioned, and on the stand of H. Jenks, Ltd., there is a working model of another practical arrangement known as the "Correcta," and made by Correcta Light, Ltd. This is certainly an ingenious contrivance at present, however, it is only standardized for Morris and Rolls-Royce cars.

The Improvement in Tyre Life

Since the war there has been a remarkable change for the better in pneumatic tyre manufacture. Nowadays one rarely meets with a car hung up on the road owing to puncture or other tyre trouble, and although this may to some extent be due to the improved roads there is no doubt that tyres themselves are also very much better and more capable of giving a long period of satisfactory service with a minimum of attention. It is pleasant to observe, however, that tyre manufacturers are not content with their achievement up to date, in addition to lowering the cost, they are continuing to strive for something better. Thus, by way of example, it may be mentioned that the Dunlop Rubber Company, Ltd., have lately

introduced a specially strong new tyre, named the Dunlop "Fort," designed to meet unduly arduous conditions.

Regular Testing of Tyre Pressure

One realizes at the show how general has become the use of balloon and low-pressure pneumatic tyres. These, while possessing undoubted advantages over the high-pressure variety, have the drawback that the margin between correct and insufficient inflation is very small. To obtain good results from them car-owners must therefore pay more regard to the details of inflation, motor owners are recommended to test their tyres once a week. Besides the well-known Schrader, there are now several air-pressure testing devices on the market, and one or other of these should find a place in every doctor's tool-kit. All these devices suffer, however, from the drawback that their use entails the removal, and subsequent replacement, of the large and small caps of the four tyre valves. During the past summer the writer has found the "Pressometer" tyre tester, marketed by T. B. Andre and Co., Ltd., a very convenient little device. It is claimed that by merely pressing this on the outside of the tyre a correct reading of the internal pressure is given on the indicator. Although one is not entirely convinced of this, there can be no question but that it is a useful and simply applied comparative gauge. The writer pumps up his tyres to the recommended pressure, obtaining this by means of the more orthodox pressure gauge. As soon as each tyre is pumped up, and the valve caps are replaced, he uses the "Pressometer" and makes a note of the position of the indicating finger. It is then easy to practise the weekly test, pressing with the "Pressometer" on each of the tyres in turn. If the finger reaches the same mark as before he is satisfied that everything is in order, if not, he knows at once that the tyre needs a few strokes of the pump.

MEDICAL SICKNESS, ANNUITY AND LIFE ASSURANCE SOCIETY

The annual general meeting of the Medical Sickness, Annuity and Life Assurance Society was held at the First Avenue Hotel, High Holborn, W.C., on October 8th, under the chairmanship of Dr. F. J. Allan.

The Chairman's Address

In presenting the directors' report the chairman said that the Society continued to make steady progress. In the last year the number of applications had trebled. The bonus declared last year had greatly stimulated interest, and the amount of new business surpassed all previous records. The schemes for practice purchase and house purchase which had been inaugurated had proved very helpful. The number of applications to partake in the practice purchase scheme had increased to such an extent that the directors considered it advisable to limit the amount of capital to be devoted to it until further experience had been gained. The scheme had been quite satisfactory, inasmuch as the interests of the Society and also of the purchaser were considered. In some cases investigation had shown that the practice proposed for purchase was not exactly suitable. Grateful letters had been received from young men thanking the Society for the assistance afforded them in giving them a fair start in their careers. There was also an increasing number of applications for the house purchase scheme. As the terms offered were generous, particular care had to be exercised regarding the value and condition of the property, the Society acted only after receiving the report and advice of its surveyors.

The first half of the past year with its depressing climatic conditions had produced claims on the sickness fund considerably above the average, but this had been counterbalanced by the healthier conditions of the second half. Thus, the amount paid out in sickness claims for the twelve months, in spite of the increased membership, was rather less than in the previous year—namely, £31,179, as against £31,225. In sickness insurance many more problems arose than with life assurance. It had been found that quite good lives from a life assurance point of view might be liable to a greater amount of illness than the average. Though the illnesses were of a minor nature, they entailed claims on the funds, and were very difficult to estimate. It was proposed to issue to members a questionnaire regarding certain minor diseases, and it was hoped that the answers would be helpful in conducting the work of the Society. The number of claims for neurasthenia had increased.

Acting on the advice of the actuary the directors had transferred to a separate fund the sum which, with interest and

dividends accruing, was calculated to meet bonus payments as they arose. The new life insurance business, which amounted to nearly £200,000, showed a gratifying increase, especially when it was remembered that this branch only started on its present basis eight years ago. The total premiums were £30,844, against £25,286 the previous year. Regarding the investments, the directors had written down some of the stocks, it was hoped that it would not be necessary to do so again. Notwithstanding this, the value of the Society's investments was nearly £24,000 in excess of that shown in the books. The continued increase in membership naturally meant an increase in management expenses, but this was not an undue amount, as was shown by the fact that during the year the expense ratio dropped from 14.19 per cent to 13.88 per cent, and, excluding valuation expenses, to 13.35 per cent. Though a complete valuation of the Society's business was made every five years the actuary examined closely the experience of the Society every year and reported thereon, so that the directors might know exactly how the Society stood. The actuary had just completed his examination and valuation and concluded his report thereon by the following statement: "This is a most satisfactory state of affairs and warrants the declaration on the part of the directors of a guarantee of the maintenance of the interim bonus at the full rate of bonus declared at the last valuation. Acting on this assurance the directors recommended the payment of an interim bonus."

Several questions about items of expenses having been answered the report was adopted. A prolonged discussion took place regarding the appointment of two directors, and it was ultimately decided to take a poll of the members. Messrs Harber, Sturges, and Fraser were reappointed auditors for one year. The meeting adopted the recommendation of the directors for the payment of an interim bonus on all with-profit policies for permanent sickness and accident insurance and life assurances becoming claims during the year July 1st, 1928—June 30th, 1929. A vote of thanks to the staff for their valuable services was adopted on the motion of the CHAIRMAN and a hearty vote of thanks to the chairman for presiding was proposed by Dr JOHN MATTHEWS and seconded by Sir WILLIAM WILCOX.

Scotland.

Tribute to Sir Donald MacAlister

IN recognition of his twenty-one years' service as Principal and Vice-Chancellor of the University of Glasgow Sir Donald MacAlister was, on October 12th, the guest of honour at a banquet, over which Lord Maclay presided, in the Central Hotel, Glasgow. There were present members of the Government, representatives of the city and its varied interests, and of the learned professions, including many medical men of note. The toast of the evening was proposed by Sir John M. Macleod, who said that Sir Donald MacAlister's brilliant career was on full record, so that anyone who ran could read it, provided he had good breath and some time at his command. He would find in it an arresting statement. It would be seen that in his day Sir Donald had been accorded every honourable academic title it was possible for a man to enjoy, not only from the great British centres of learning, but from those of the Dominions and from ancient and famous seats of culture in Europe and America. Continuing, Sir John referred to the growth of the University since 1907, when Sir Donald MacAlister was appointed, saying that at that time there were 2,504 students, and last year there were 5,294. To meet this heavy increase there had been appointed 18 additional professors, 90 lecturers, and 31 assistants. These figures gave some idea of the additional work now being done at the University under the Principal's moving and guiding inspiration. All he had touched on could only have been achieved by the driving force of Sir Donald's personality, his enthusiasm, and, above all, his poetic temperament, all of which, he was proud to believe, was derived largely from the fact that his blood was strong because his heart was Highland. Sir Donald MacAlister replied in a racy speech, in which he dwelt upon the close relationship existing between the city and the University in Glasgow, and upon the way in which the citizens had given their support to the work of the institution of which he is Principal. The citizens of Glasgow, he said, deemed nothing that was human, including humane studies in the widest sense, to be outwith their concern or beyond the scope of their fostering care, the Lord Provost and magistrates took part in the

work of the University. Count Glasgow magnates and merchants, and lawyers and doctors, and teachers, gave of their time and thought to its day-to-day administration. The Lord Provost, Sir David Mason, replying to the toast of "The City of Glasgow," proposed by the Earl of Elgin, referred to "the consistently noble manner in which their guest had supported the Corporation in every movement for the material welfare of the community", while Sir Alfred Ewing, Principal and Vice-Chancellor of Edinburgh University, spoke of Sir Donald as the doyen of the vice-chancellors of the universities of Great Britain and the keeper of the professional conscience of the doctors of this island. But his great work, Sir Alfred Ewing said, had been his guidance and administration of Glasgow University, it had indeed been a great work, great in every step and great in its results. Dr Walter Elliot, Under Secretary of State for Scotland, said that he bore to Sir Donald the good wishes and congratulations of the Secretary of State for Scotland, and recalled that the last similar gathering in the life of Glasgow had been some thirty years ago, when a banquet was held to do honour to Lord Kelvin. The proceedings closed with the toast of "Lady MacAlister," who was the only lady present.

Royal Medical Society of Edinburgh

The 1928 session of the Royal Medical Society of Edinburgh was opened on October 12th by an inaugural address from Sir John Robertson, M.D., of Birmingham. Dr W. Mitchell Innes, senior president of the society presided. The lecturer took as his subject the borderline between preventive and curative medicine, and remarked that these two branches of medicine had in the past been kept much too far apart. There was still too little consideration given by doctors to the prevention of disease, while those who were engaged solely in preventive work laboured under the disadvantage of not being in intimate contact with the sick. It might be said, comparing the present day with fifty years ago, that from 30 to 50 per cent of deaths were now avoided every year. This saving meant that the average expectation of life which every person had at birth had been extended by fifteen years. Many causes had combined to produce this result, but of these the two most important had been the daily teaching of the ordinary doctor in the consulting room and in the homes of the people, and the vastly improved intelligence of the people, which had enabled them to appreciate the information gained during sickness. The value of such measures as the provision of good water supply, drainage, scavenging, and so on must not be overlooked, but all these things had been rendered possible only by the greater knowledge among the people. The clinician, who was in constant attendance on the sick and could inquire into the cause of illness, was almost the only person who was able to suggest means of preventing a large variety of illnesses. His observations and experience were not yet collected and used sufficiently for the general good, and some organization was necessary to sift the value of these clinical experiences. The methods now used in reducing infant mortality formed a good instance of what could be accomplished by simple instruction, and the mortality had been halved in twenty-five years by telling mothers how they ought to rear and feed babies. Was it possible, for example, the lecturer asked, to prevent the condition known as flat-foot, which, though simple, caused an immense amount of unemployment and discomfort? No less than 27 per cent of recruits in one of our large police forces had been due to foot troubles. The profession, he felt sure, could undertake no inquiry as to how these might be prevented. Much was being done by factory surgeons, school medical service, and health authorities, but none of these quite got down to the conditions under which disease originated. There were two organizations, however, which might be useful for the type of inquiry necessary. These were the national health insurance scheme, which had the object not only of treating sick persons, but the prevention of disease, although the latter question so far had been neglected, and the Medical Research Council. All such inquiry and organization of the profession must occupy considerable time and must be carefully tested, but in the absence of such an attempt he was sure that they were losing time in getting a greatly

improved state of the health and physique of the people. A vote of thanks was accorded to the lecturer on the motion of Sir Robert Philp.

Aberdeen Chair of Physiology

Professor J J R MacLeod, who has succeeded Professor MacWilliam in the chair of physiology at Aberdeen University, delivered his inaugural lecture on October 10th. Professor Low, dean of the medical faculty, who presided, referred to Professor MacLeod's early connexion with Marischal College, where he had graduated thirty years ago. He also recalled the part Professor MacLeod had played in the discovery of insulin, and the establishment of its efficacy in diabetes, for which, along with Dr Banting, he had been awarded the Nobel Prize for medicine in 1923. Professor MacLeod said that it had always been his ambition that he might return to Aberdeen to hold this chair and to enjoy the great opportunities for physiological research which the University of Aberdeen offered, and which had been greatly enhanced by its close connexion with the Rowett Institute and the proposed new hospitals. He considered that the medical curriculum of to-day was overburdened with detail, and that the relationship of one subject to another was not sufficiently adjusted. He thought also that more might be done to emphasize the importance of combining scientific reasoning with clinical experience, and that there was a great advantage in having men with a scientific training on the clinical staffs of hospitals, both in regard to the treatment of the patients and the instruction of medical students.

Post-graduate Courses in Glasgow

The arrangements made by the Glasgow Post-Graduate Medical Association for the coming winter months are on similar lines to those of recent years. A series of demonstrations will again be given on Wednesday afternoons, from November 7th to May 29th, for practitioners who desire to keep in touch with recent advances in medicine, surgery, obstetrics, and various special departments, the fee for the course is three guineas. Special courses in ophthalmology at the Glasgow Eye Infirmary—particulars of which may be obtained from the medical superintendent of that institution—include a slit-lamp course for ophthalmic surgeons in November and December, and a diploma course extending from January to May. Eight demonstrations on chronic diseases and end results will be given by the visiting staff at Stobhill Hospital on Monday and Friday afternoons in November, the fee being one guinea. Professor Leonard Findlay, Dr James Hendry, and Dr J N Cruickshank will co-operate in a course on "The mother and the newborn infant," clinical meetings and demonstrations being held at various institutions on Tuesday and Friday afternoons from November 20th to December 14th, the fee is two guineas. A series of demonstrations by the staff of the Ear, Nose, and Throat Hospital will begin on April 16th, continuing on Tuesdays and Thursdays for about a month. A limited number of clinical assistantships are available during the winter months in institutions connected with the association. Further details may be obtained from the secretary, Dr James Carslaw, 9, Woodside Terrace, Glasgow, C3.

England and Wales.

University College Hospital Medical School

THE annual "Past and Present" dinner of University College Hospital was held at the Hotel Cecil on October 12th, under the chairmanship of Surgeon Vice-Admiral Gaskell, C.B., Medical-Director, R.N. More than usual interest attached to this dinner because it marked the centenary of the Medical School and of the Medical Faculty of University College, which had been celebrated during the day by a series of special demonstrations arranged for the benefit of old students. The chairman, in proposing the toast of prosperity to University College Hospital Medical School, spoke of his pride as a former student in being asked to preside on this great occasion in the history of his old school. A characteristic he

shared with all U.C.H. men was their love of Alma Mater and then delight in her continued success. The dean, Dr A. M. H. Gray, in his reply, gave a brief account of the doings of the Hospital and School during the past year. Noteworthy events had been the completion of the new hospital buildings, the acceptance by H.R.H. Prince George of the Presidency of the Hospital, and the award of a Royal Medal of the Royal Society to Sir Thomas Lewis. The ontry of new students was larger this term than in any recent year, and there had been inaugurated that day an old students' club. In conclusion, Dr Gray referred with sorrow to the deaths of Sir Dawson Williams and Dr Walter Rigden, who had both presided over dinners in past years. The health of the chairman was proposed by Sir John Rose Bradford, President of the Royal College of Physicians, who said that they often dined out together and sat near each other on public occasions, but the best reason for entrusting him with this toast was that Admiral Gaskell and he were very old friends. University College Hospital was proud of Admiral Gaskell's fine services to the country in many parts of the world, and of the distinguished position he held to-day. The chairman, in brief acknowledgement, offered the thanks of all present to Dr F. M. R. Walshe and Mr T. K. Martin, the honorary secretaries of this most successful dinner. Dr Herbert Spencer has been elected president of the old students' club, and Dr Glyn Hughes secretary, all communications relative to the club should be addressed to the latter at the Medical School, University Street, W.C.1.

Health and Education

The new clinics at Bury, in Lancashire, which are to be used for the work of the Health and Education Committees of the borough, and also as a maternity and child welfare centre, were formally opened on October 10th by Dr H. B. Brackenbury, Chairman of Council of the British Medical Association and Vice President of the Association of Education Committees for England and Wales. The mayor Alderman S. H. Wilkinson, who presided, said that, with the exception of the dental clinic, the services which were being inaugurated were not new, but they were being transferred to better premises. Dr Brackenbury, in his address, discussed the real meaning of health and the relations to one another of health administration and educational administration. Health, he said, was not merely freedom from disease, they aimed now not merely to cure the ills that came upon them, but more and more to prevent these ills. But health was even more than that, he hoped and believed it was coming to mean the full development of all the powers of body and mind and even of personality. That being so, it must be clear to them that health and education were not two separate departments, but merely aspects of the same thing. Therefore, in pursuing their object of perfect health, the administrator—to whom he gave no mean place—the teacher, and the doctor were all parts of the same machinery, and were not working independently. The institution they had met to open was part—but only part—of the machinery which was being used to promote the perfect health of the community, and the combination of its varied activities under one roof would promote the convenience and comfort of everybody, and be economical as well. Dr Brackenbury discussed the functions of the clinics, emphasizing the importance of ante natal attention, either at the centre or elsewhere, as a means of reducing maternal mortality and illness, and pointing out that it was not to be expected that everyone would use the clinic. He believed that if people could make provision for themselves it was the best way, rather than to call on public funds. They must, to carry out the idea of unification of services effectively, interest the teachers and doctors in the institution. The reports of the health examination of the children at school, the treatment and advice they received, must be brought to the notice of the teachers, he hoped they were not so foolish in Bury as to have classes so large that the teacher could not be interested in each individual of whom he had the oversight. He hoped also that they were using the school as another part of the health machinery by insisting that every child should have proper, efficient, practical instruction in matters of personal hygiene. Further, Dr Brackenbury

said, they had to interest the doctors in the institution because it was only part of the work of the town. Doctors did their work in their own way or in other departments of public health, all were working along with the institution to produce the results which were the aim of all. He thought they should utilize the doctors of the town in the work of the institution as far as possible. Although there were limitations, the greater part of the work of a clinic of the kind could, in his opinion, best be done by the doctors of the locality itself. This had the advantage of an intimate connexion between the home where the doctor went and the work done within the institution. There was no method of producing the results desired except by unity and co-operation, they should put the institution in its right place in connexion with other people working towards the same end in the schools and homes. The best thing he could wish them was that it would become more and more unnecessary, they should not look upon it as a thing to be proud of for its size. Dr. I. W. Johnson, chairman of the Health Committee, in proposing a vote of thanks to Dr. Brackenbury and the mayor, said that the union of clinics had been brought about by the Health and Education Committees. The former body, guided by its medical officer, tried to work in conjunction with the medical men of the town on every possible occasion. They gave no treatment at the welfare centre except in cases referred thereto by their own doctors.

National Association of Insurance Committees

The sixteenth annual meeting of the National Association of Insurance Committees (which, with a membership of 125, includes all the Insurance Committees in England except four) will be held in the Hearts of Oak Building, Euston Road, London, on October 25th, 26th, and 27th. On the second day of the proceedings the meeting will be addressed by Mr. Michael Heseltine, while at the closing session on Saturday morning Professor H. R. Kenwood, chairman of the Central Council for Health Education, will speak on the work of that body, and Professor W. W. Jameson will give an address on health education. Among the representatives appointed to attend the meeting are a considerable number of medical practitioners. The annual report of the council to be considered by the meeting, refers to many aspects of insurance administration, and in particular to the discussion between the representatives of the association and the Ministry of Health during the formulation and passage of the Insurance Act of this year. In connexion with the question of prescribing by insurance practitioners, mention is made of the action taken by the Insurance Acts Committee of the British Medical Association in consequence of the revision of the arrangement between the pharmacists and the Ministry of Health last year. The investigation of prescribing is the subject of motions put forward by the Insurance Committees of East Sussex and Lancashire, the former body suggesting that the Association of Insurance Committees should urge upon the Ministry of Health that regional medical officers, in any interviews they may have with doctors in reference to prescribing, should confine themselves strictly to inquiries with regard to prescriptions issued by the practitioner, and should not lay down standards of prescribing, and further, that the Ministry, before taking any official action of a disciplinary nature, should refer the matter to the Panel Committee for its consideration. The Cheshire motion proposes the amendment of Article 37 of the Medical Benefit Consolidated Regulations, 1924, to provide for Insurance Committees being associated in the investigation of the prescribing of insurance practitioners from the point at which, under Clause I of that article, a *prima facie* case is referred to the Minister. In its report the council expresses regret that the recent amending Insurance Act makes no provision for adequate funds to enable Insurance Committees to carry out effectively the systematic education of insured persons on questions of personal health. A recommendation of the council is to the effect that the association should renew its demand for an adequate nursing service to be available to all persons entitled to medical benefit.

Ireland.

Royal Victoria Hospital, Belfast Opening of the Winter Session

THE address at the opening of the winter session at the Royal Victoria Hospital, Belfast, was delivered by His Honour Judge Thompson, Recorder of Belfast, on October 11th, in the King Edward Memorial Hall of the hospital. Professor Fullerton presided, and on behalf of the visiting staff welcomed the students. The Recorder said that his being there was an innovation, and he thought he could foresee a clergyman, an accountant, or a stockbroker coming to address them in future years. A lawyer's orbit, like a doctor's, touched nearly every aspect of human life, and often the doctor's and the lawyer's orbits intersected. This had given rise to medical jurisprudence, on which he wished to speak. By medical jurisprudence he meant the intersection which occurred when the lawyer's knowledge and interest came into contact with the doctor's—when the aid of medical science was called in in the detection of crime or in the assessment of damages for personal injuries. There had been in the past some great medical jurists, though some of them were rather in the nature of swearing gladiators, and were in everything but name, advocates, they should set before themselves the ideal that they, as witnesses, were there to assist the court, not merely to assist client or patient. They should not let themselves be persuaded to take cases "on spec", their evidence should not depend on whether their clients won or lost. If they got into that position they had surrendered their proper position before the court. The qualifications of the good medical witness were his medical and his general qualifications, and from the point of view of the court the latter were often the more important. They should know how people lived—how they carried on their trade. They should visit, inspect, and examine the machinery in case of an accident and make up their minds whether it could have been caused in the way the patient stated, they must know the meaning of the technical terms used by the patients. How the injury was caused was of vital importance. The extern or outpatient department of a hospital was an excellent school from that point of view, for there every day they met people who sustained injuries in every kind of work. The court wanted results, not diagnoses or symptoms alone, because it had to decide to what extent the injury existed. They should not be too technical—a mark of the young doctor—but they should be thorough and take a note of everything, no matter how trivial, and pay especial attention to dates. When they had made up their minds, they should stick to the opinion they had formed, they should always be in time, and, if at all possible, sit throughout the hearing of the case. Professor R. J. Johnstone proposed a hearty vote of thanks to the Recorder for his wise and witty advice. This was seconded by Dr. J. S. Morrow, who said that His Honour had a great understanding of medical men as well as a great sympathy with them.

Belfast Samaritan Hospital Extension

On October 12th, during her recent visit to Ireland, Princess Mary opened an extension at the Belfast Samaritan Hospital. At the opening ceremony Miss F. L. Henderson, president of the hospital, said that it was the only hospital in Ireland exclusively for the treatment of women, in the old building splendid work had been carried on for over fifty years. About fifteen years ago it became evident that something should be done to enlarge and renovate the building, but the war intervened and it was only within the past few years that they had been able to contemplate the absolutely necessary extension. She expressed the opinion that the operating unit was the most perfectly equipped any surgeon could desire, while the large public wards, as well as the private wards, were fitted with every modern convenience and comfort for the patients. Miss Henderson concluded by referring to the services to the hospital of Viscount and Viscountess Craigavon and Mrs. W. R. Mackenzie, the honorary secretary. Sir John

Campbell, M P, senior surgeon, traced the history of the hospital from its foundation in 1872 by the late Dr W K McKordie in a house, and the erection of the present building by Mr Edward Benn two years later, when provision was made for paying patients. The work of the institution, he said, had steadily increased, patients had been received from the whole of Ulster, and from places further afield. Princess Mary declared the hospital open, congratulating those concerned on the success of their efforts, she expressed the hope that the people of Northern Ireland would continue to subscribe liberally to the funds, and thereby keep the Samaritan Hospital in as efficient a state as modern medical science demanded. A vote of thanks to Princess Mary was proposed by Viscountess Craigavon.

Epidemiology in Ireland

Sir John W Moore's address on "Epidemiology in Ireland Past and Present," which was given at a sectional meeting of the congress of the Royal Institute of Public Health in Dublin in August, and has been published in the October number of the *Irish Journal of Medical Science*, gives an erudite survey of this aspect of medicine from the earliest times. He recalls that the earliest recorded pestilence in Ireland has been referred by the Irish annalists, the Four Masters, to the year of the world 2820, tumult marking the burial place of the victims of the epidemic which occurred then can still be seen near Dublin. From these remote times Sir John Moore passes to the beginning, towards the close of the seventeenth century, of the scientific study of disease and mortality with which the versatile Sir William Petty was associated. After reviewing the subsequent history of epidemiology in Ireland the writer brings his survey down to the present time with the record of his personal experiences and studies, and those of his contemporaries, during the past sixty years, in the earliest part of which voluntary effort proved an important factor in awakening the public consciousness to the need for sanitation and effective public health organization. Among the agencies which were engaged upon this work was a sanitary commission appointed by the *Freeman's Journal*—the leader of so many important movements in the past in Ireland—in 1873, on which Sir John Moore served as a member. He recalls that Dublin University instituted a diploma in State medicine in 1870. Four candidates were successful at the first examination, held in June, 1871, in which year Sir John Moore himself gained the diploma.

Correspondence.

THE "MEDICAL REGISTER"

SIR,—Voting papers in connexion with the election of Direct Representatives will be issued to-morrow (Saturday, October 20th) to all practitioners having registered addresses in England and Wales. Any such practitioner who does not receive a voting paper in course of post, whether he wishes to vote in the election or not, should immediately communicate with this office, in order to ascertain that his address is correctly entered in the Register—I am, etc,

44 Hallam Street Portland
Place W.I. Oct. 19th.

NORMAN C KING,
Registrar General Medical Council

FUNCTION AND POSTURE

SIR,—Your issue of September 22nd contained the report of an address by Dr W Colin Mackenzie of Australia, the importance of which can hardly be exaggerated. It also contained a leading article on his address in which his main conclusions are assented to, and, indeed, endorsed, this leader, both intrinsically and also as giving the opinion of the principal medical journal of our day, is of hardly less importance.

The gist of Dr Mackenzie's address is to emphasize the importance of the way in which the human organism functions as affecting the health of the organism, to deplore the neglect of the study of function in our present-day practice of medicine, to assert, with a considerable amount of evidence, that progress in the evolutionary

scale is associated with the "erect posture," and that the "erect posture" is still unstable, implying that the functioning of the neuro-muscular elements maintaining it is imperfect.

The address, as also your leader on it, was of all the greater interest to me inasmuch as you published on December 25th, 1926, a cognate address delivered by myself to one of the Association's important Branches, when I had the honour to be its president, on "Instinct and functioning in health and disease." In it I myself made no original contribution to the subject, but I endeavoured to attract the attention of the profession to the work of F Mathias Alexander, who has, by quite independent methods, arrived, with other things, at the conclusions reached by Dr Mackenzie, but has also done much more, inasmuch as he has evolved a technique by which he can teach his pupils a right—or rather a better—functioning. In some ways his work is the most important of our time, with a wide bearing, not only on the science and art of medicine, but also on education, philosophy, psychology, and, indeed, sociology—in which opinion I know that Professor Dewey, the famous American philosopher, agrees.

It would seem from Alexander's work that "Homo Erectus" has not yet fully learnt the "erect posture," and that he can do so only by conscious, as distinct from instinctive, effort, and to teach this conscious control is Alexander's aim. My own observations on his work lead me to believe that right functioning is the most important factor in the prevention of disease, and an improvement in functioning—in which I would include as the most important a knowledge how to walk, stand, sit, run, breathe—not only tends to prevent disease, but often to eliminate (that is, cure) disease already established. That cure is then a real one, for it follows from the removal of the cause of the disease, not, as when a surgeon takes away an inflamed appendix or a cataract, from the removal of a result of disease.

There is a danger of this important work being lost. Alexander is not now a young man in years, only a part of his teaching can ever, from its very nature, be obtained from books. As I pointed out in my own article—"words cannot be used to convey any meaning as to a sensory appreciation." If it be not lost, but incorporated into the education of the young, it is likely to do much for progress in the evolution of humanity. If it be lost, that loss may be permanent, or until another genius like Alexander is born to resuscitate it. In the history of the evolution of humanity such are rare areas. Thus medical generation will then have the reproach cast, and rightly cast, on it, that it failed to recognize the prophet in his own country and in his own time—I am, etc,

York Oct 13th

PETER MACDONALD, M D

THE POPULATION PROBLEM IN TERMS OF ENERGY

SIR,—In the interesting discussion at the Cardiff Meeting on "The falling birth rate," the opening papers of which were published in the *British Medical Journal* on September 15th, the problem of population, though considered from many angles, was not analysed in terms of energy. This I consider the most fundamental aspect, for it can hardly be denied that life, whatever else be grafted on to it, is a manifestation of the law that energy tends to degrade.

Further, it can be observed that whenever a source of energy becomes available a population of creatures eventually appears which exploits that energy till it is degraded more or less completely. Even the energy of sulphuretted hydrogen water of volcanic springs has its appropriate bacillus to live and grow upon it.

In the older simpler human communities the energy available was that which could be caught by hunting or fishing, or trapped from the sunshine and converted into food agriculturally. Then, in this country, came a great change. The immense fossilized stores of solar energy in the form of coal were not digestible by any creature till man created various Frankenstein monsters in the shape of engines which could digest this "food" and turn its energy into useful work.

Rapidly the industrial era developed by exploiting fossil energy, and far larger families could be reared and find work than was possible on an agricultural basis. More recently other countries learnt to do the same thing—often more cheaply—and a rapid decline in our rate of reproduction has become necessary. Some politicians seem scarcely to recognize that we must sell the proceeds of this energy abroad, or starve, or reduce the population. They speak of the "right to work" in terms of energy: there is no such right. It is rather the privilege of exploiting some source of energy which may be available for them or perhaps a limited number of their children.

Wild creatures seem to recognize this truth. In the great swannery at Abbotsbury in Dorset I read that the cock swans line up and kill nearly all the cygnets on their way to the water. Presumably they realize that the energy supply of their lake is already fully exploited. Even bacteria seem (to me) to have a remedy for over-population, for after cultivation for ten days on broth they develop an antiviral which inhibits further growth. This substance is now being utilized clinically.

Let us next consider money in terms of energy. To my mind it is analogous to light or other radiant energy, for there is practically no energy in light till it hits matter and sets its molecules in altered motion. Similarly, there is no energy in gold till it has passed from someone who possessed some source of energy to another who will convert it again into work. Gold is peculiarly useless except to dentists. So that money and light seem to be energy in transit. Let us apply this to the dole of the unfortunate recipients not receiving money which has, as it were, no foundation in energy—no existence in goods and services. This drains the strength of the working community and hampers its competition with energy exploiters in other countries. At present this may be endurable, but soon it will become insupportable. For, bearing in mind the rule that a source of energy will acquire a population to exploit it, we shall find that the dole will produce families, and the whole community will in time be swamped if it flouts the laws of energy in this way.

Certain extremists are now trying to catch votes by promising increased doles with extras for every child. Such leaders must consider their actions in terms of energy. It sounds horribly merciless, but far less than the consequent ruin and starvation. It seems obvious that this island is already over-populated and that the voluntary control of the birth rate is intended to minimize this evil; it should be made more available to the poor.

To sum up, I submit that the problems of population and birth control can best be studied fundamentally in terms of energy.—I am, etc.,

Hull Oct 1st.

F C EVE

THE DEFINITION OF DRUNKENNESS

SIR,—I have just returned from the quarter sessions at Clchester. I was engaged as police surgeon to give evidence against a man charged with being "drunk in charge of a motor cycle." I had seen him previously at the police station, when I certified him "not to be drunk in the ordinary sense, but not fit to be in charge of a motor cycle." A second doctor, called in at my suggestion as the man was not satisfied, agreed with my statement entirely.

The chairman of the quarter sessions, a well-known K.C., in addressing the grand jury emphasized the fact that there is only the distinction in law of being (1) drunk, or (2) not drunk, the condition cannot be qualified by "not fit to ride a motor cycle." In law doubtless he is right. The grand jury accepted his view, and failed to return a true bill.

What is my position? I live on what is probably one of the most congested motor traffic roads in England. When called by the police I have now to decide only whether the man is "police-court drunk," and if not satisfied I have to authorize the police to let the culprit go. In this case the man had in his possession a pint of port, and freedom meant drinking it and riding off on his cycle.

Unless and until there is a drastic change in the law I shall have only to decide whether the man is drunk or not drunk, and, whatever my opinion may be as to his

fitness to drive, I shall be compelled to allow him to go if he passes the "drunk" tests, and thereby I shall help to increase the number of accidents, which are already growing daily.—I am, etc.,

Crawley Oct 11th

SIDNEY MATTHEWS, J.P.

MEDICINE AND FLYING IN AUSTRALIA

SIR,—In the *British Medical Journal* of July 7th (p. 25) it is mentioned that Sir Samuel Hoare, when presenting the prizes at the London Hospital on June 29th, pleaded that the medical service of the Royal Air Force should be considered not only as an integral part of the "new arm," but as an important branch of the medical profession.

I am writing now to inform members of the British Medical Association that an aerial medical service is in actual existence in the north of Australia, the northern parts of Queensland and of New South Wales, and the Northern Territory. The Presbyterian Church of Australia initiated this service some three years ago, a long time was spent in preparation. In the meantime the necessary subscriptions had been obtained for the first year's full service, and then a request was received by the Victorian Branch of the B.M.A. that a medical man should be appointed to the board of the Australian Inland Flying Mission.

The first aerial medical officer was selected on February 22nd, 1928, there were twenty applicants. The term of service was for one year, the salary was £1,000 per annum plus expenses, and no private practice was allowed. Each district under the scheme is joined up by wireless or by ordinary telegraph service to the centre at Cloncurry, Queensland. The board of the Australian Inland Mission has made financial arrangements with the Queensland and Northern Territory Aerial Service, and at Cloncurry the aerial medical officer has an aeroplane always ready (a De Havilland 50), large enough to hold himself, the pilot, a stretcher, a nurse, and the patient. The average distance of the calls will be under 400 miles.

Dr K. St. Vincent Welch is now on active duty in that region, we hope very shortly that a report of his first year's work will be published, and will make a worthy record of service in this new land. To many of us this work is of a kindred nature to that undertaken at Labrador by Sir Wilfred Grenfell and in Kashmir by the Neve brothers.

Please note that the flying medical officer in no way interferes or competes with other medical practitioners, who are sparsely situated, sometimes 100 to 150 miles from each other. When summoned to a sick patient the flying doctor takes the aeroplane and pilot, stretcher, and nurse, and if possible brings the patient to the nearest hospital, leaving him or her in charge of the local doctor, rendering such assistance as is in his power, and even staying to give an anaesthetic or assist the doctor in any work necessary.

Medical committees have been formed in Adelaide, Melbourne, Sydney and Brisbane to consult with and advise the Australian Inland Mission, so that the whole scheme is now organized.

This work has been explained to Dr. Haden Gnest, who was recently in Australia and took back maps with him to London, Dr. Beveridge hopes to introduce something like this scheme into Uganda.—I am, etc.

Melbourne Australia

J. W. DUNBAR HOOPER, M.D.

ANAESTHESIA FOR TONSILLECTOMY AND REMOVAL OF ADENOIDS

SIR,—In the correspondence that has taken place on this subject during the past few months, most of the writers seem to have assumed that, where tonsils and adenoids were enlarged or diseased, their removal was all that was necessary to bring about a cure and to restore the child to its normal health.

The "lust for speed" appears to have spread to operators, some of whom seem to boast that they hold the "record" for the number of cases they can get through in an hour. But little mention is made of "results." They do not state how many of these children are restored to normal health and how many are not. This, I think you

will agree, is an important point, and I should like, as a general practitioner who follows up many of these cases, to offer a few observations.

It has not infrequently been my experience that children who have had their tonsils and adenoids removed by experts have not been cured, and, in fact, have been little better for the operation. Such children suffer from chronic nasal infection with persistent discharge, liability to severe "colds," attacks of bronchitis, and general ill health, which seriously interferes with their development and education. This, I think, is generally due to sinus infection, which has to be dealt with before the trouble clears up. In fact, I believe that quite a large proportion of children with enlarged tonsils and adenoids do suffer from sinusitis, and in order to make the operation for their removal a success the nasal sinuses should be explored and, if necessary, washed out. This can quite easily be done if ether is administered, but obviously it cannot be if such a transient anaesthetic agent as ethyl chloride is used.

On this point I should be glad to have the comments of some of your previous correspondents—I am, etc.,

W R SOMERSET, M B, Ch B

Wolverhampton Oct 7th.

TUBERCULOSIS SERVICE

SIR,—May I suggest that those taking up an appointment at a sanatorium, under a county or other administrative body, should adopt the following precautions:

1. To be medically examined by someone whose opinion will carry some weight.
2. To have a good skiagram taken of the chest.
3. To obtain a clear understanding as to the course of action the committee concerned will take should he or she develop tuberculosis.
4. To take out or better still insist that the committee take out for him or her a medical sickness insurance policy.

There are public bodies who will not admit any liability, nor will they make any provision for treatment, should a member of their staff develop tuberculosis whilst in their service, except to grant a variable period of sick leave.

Thus, unless these precautions are taken, anyone holding an appointment at a sanatorium who is unfortunate enough to develop tuberculosis will have his or her appointment terminated, either immediately or following a short period of sick leave. Moreover, no provision will be made for his or her treatment—I am, etc.,

Devon Oct. 10th.

ALAN J McFILLAN

TUBERCULOSIS IN CHINA

SIR,—In the report of Dr Hoyte's address at the Medical Missionary Breakfast at the Annual Meeting at Cardiff (Supplement, August 4th, p 86) mention is made of the ravages caused by tuberculosis in China, "an interesting point in view of the fact that milk is very little drunk."

Now in making a précis of the address certain relevant points may have been lost, but the above statement is too inaccurate in its implications to be allowed to pass without criticism and a statement of the facts as known to us in the East.

No one disputes that tuberculosis is a scourge among the Chinese, or that these people, for several reasons, chiefly economic, do not drink much milk. But, even if they did drink milk, the tuberculosis morbidity rate would be much the same, for tuberculous cattle are few, thus there were 23 condemnations out of 40,000 slaughtered cattle (Shanghai Municipal Report of last year).

As we find tuberculosis, it is an infection with the human type of germ, and it is spread in the usual way by coughing and spitting unrestrainedly, indiscriminately, inside dwellings, and in public places. No other method of propagation of this disease need be considered or discussed as regards the Chinese.

The "interesting point" in fact is this: that education and isolation of the sick would be more likely to eradicate quickly the disease in the Orient than in carefully administered Britain! And this for the reason that children here are not being supplied with tuberculous milk from fourth-

rate and filthy dairies untouched by a legislation that shudders at the idea of anything "in discouragement of trade."

I hear of the new slogan with you at home, "Drink more milk," and I read in your issue of August 4th (p 216) of that dairy in Hertfordshire! And having read thus I feel grieved that it should be suggested at a meeting of medical men that China is so very far behind in this year of grace I apologize in advance to Dr Hoyte if I have read more into the report of his speech than he intended, but (as he is no doubt aware) Dr Cobbett ascribes 30 per cent of the cases of bone and joint tuberculosis in young children in England to the bovine type of infection, is not this to an even greater degree an "interesting point in view of" (1) the number of health officials maintained, and (2) the profits of the milk trade?—I am, etc.,

A H SKINNER,

Admiralty and Customs Surgeon

Hankow, China Sept 7th.

SODIUM NITRITE IN SEA-SICKNESS

SIR,—Without entering into the complex etiology of sea sickness, but working solely on the preliminary report of Drs J Frank Percy and Daniel B Hayden on the treatment of sea-sickness by sodium nitrite (*Journal of the American Medical Association*, April 14th, 1928), the following results were obtained in a series of 100 consecutive cases treated at random with sodium nitrite:

Positive—complete relief	29
Positive-negative—partial relief	5
Negative—no relief	43
'No record'	23
	100

The salt was given in 5-grain tablets, at two-hourly intervals, for six doses. If no relief was obtained other remedies were applied. We were able to give it in 12 cases prophylactically, before even any sensation of *mal de mer* had been experienced at all, with 5 positive and 7 negative results.

In 8 cases presenting every symptom of sea-sickness short of actual emesis, its administration promptly produced vomiting. Whether this was because or in spite of the drug we were unable to decide, although the patients quite naturally attributed the sequel to it and refused to take any more. Two patients showed signs of collapse with profuse sweating and pallor within twenty minutes or so of taking the first dose. Subsequent examination of the pulse revealed a state of hypotension. Hence, as indeed in all cases of sea-sickness, a rough estimate of the blood pressure should be made prior to giving sodium nitrite. In the other cases vomiting had occurred before the drug was administered.

Cases shown as "no record" are included in this term to avoid vitiating statistics, since, presumably, they may include both positive and negative results which the patients were not sufficiently interested to report officially and which we were not in a position to follow up without unduly obtruding ourselves.

From this limited number of cases we are of opinion that sodium nitrite is by no means a specific for sea-sickness. In fact, its results do not compare with those obtained by the hypodermic injection of strychnine and atropine. A more extensive test of its value as a prophylactic—before the onset of any symptoms—would seem desirable. Its employment, however, as a routine in preference to other known remedies, when vomiting has set in, does not seem justified in our experience. It undoubtedly succeeds in some cases, but, like all other measures tested to date—"patent" or otherwise—it is far from being a specific.

That 100 cases is a small number upon which to base an opinion is frankly admitted, but, except from a prophylactic standpoint as yet to be accurately determined, the success obtained so far does not appear to warrant anything further than the inclusion of sodium nitrite in the long list of drugs already in use for this distressing condition with varying success.

At the present moment a proprietary preparation, made in Philadelphia, is being extensively advertised to North Atlantic travellers. It purports to be based on the same preliminary report regarding sodium nitrite upon which the foregoing test was made. The advertisement, however, contains a very definite saving clause to the effect that "it was later found necessary to add other ingredients." The nature of these additions is not stated, although it would be interesting to know what they are, more especially so, in view of the short time which had elapsed—three months, April to July, 1928—since the publication of this preliminary report and the appearance of the tablets on the market. Furthermore, the inclusion of other ingredients in the tablets at once nullifies the claim made for the efficacy of sodium nitrite in the preliminary report.—We are, etc.,

DEMENTIA PRAECOX IN PARSEES

SIR,—I notice in your issue of October 6th (p. 634) that a correspondent, who does not appear to have any personal knowledge of Indian conditions, has isolated one small generalizing paragraph from my article on the heredity of dementia praecox, published on September 29th (p. 566) in support of what is apparently his thesis that dementia praecox is due to "Western education" pure and simple!

Nowhere have I stated, nor is it true, that Parsee education is of a specially intensive kind. On the contrary, I have dwelt on the genius of the race for commerce, which does not demand any such type of education, and on the peculiar prevalence of the disorder among Parsees generally. I have not used the word "Europeanized," nor have I stated that any one Indian community is on a "lower" stage of civilization than another. I attempted to show in my article that the peculiar incidence of schizophrenia among Parsees was not traceable to any fault, education or environment. That "mental stress" may be an "exciting cause" of the disorder in predisposed individuals, wherever they may live, is, I think, admitted by all authorities.

Dr Brock's "common factor" for Indian communities does not therefore exist, and however much I may agree with him about the dangers of "cramping," his advice to Parsees to avoid Western civilization is not supported by anything I have written. The dangers of "inbreeding" are, however, to my mind, obvious—I am, etc.,

W S JACOB SHAW, M D,
Lieut-Colonel I M S (ret.)

Parkstone Oct 7th

SECURITY OF TENURE IN PUBLIC POSTS

SIR,—I have read with great interest the letter in your issue of September 29th (p. 587) by Dr H C McManus on security of tenure in public posts. I consider his remarks worthy of the most serious attention, and very opportune.

As the servant for some years of a local authority—namely, an asylum visiting committee—I should like to make a few remarks not only on the question of security of tenure, but also on the conditions of service of an assistant medical officer in an asylum. We hear a great deal these days about the desirable opening which the asylum service provides for newly qualified medical men and women, but we hear very little of its undesirable features. My remarks are based on my own experience and on that of others with whom I have come in contact. They apply in most respects to all asylums, but more especially to the smaller institutions.

In the first place, as Dr McManus has stated, there is no security of tenure whatever. The committee can dispense with the service of any medical officer at any time it wishes and without giving any reason. Dr McManus speaks of the position of a housemaid, but I consider the position of a housemaid in an asylum as much more secure

than that of an assistant medical officer. She is generally a member of a very powerful union, which takes care of her interests.

Then with regard to salary. The commencing salary of an assistant medical officer is £300 or £350 with board and lodgings. In a great many asylums the increments are entirely at the pleasure of the committee. Nothing is promised at the outset, and all increases must be asked for by the person interested, to be granted or refused at the committee's pleasure. It must be borne in mind that the assistant medical officer never comes in personal contact with the committee. Whatever report the medical superintendent may make is all that the members of the committee know about him. In fact, many medical superintendents take pains to prevent as far as possible any personal contact between the committee and the junior officers. In addition, a junior medical officer is always resident, and receives board and lodgings as part of his salary. The value of such emoluments varies enormously. In most of the smaller asylums it seems to be nobody's business to see that this part of the contract is carried out in a proper manner. In an experience of several years I am unable to recollect a single instance where an inquiry was made either by the medical superintendent or by the visiting committee as to the comfort of the assistant medical officer's lodgings or the quality of his food.

Furthermore, in the majority of cases the junior assistant medical officer, if he decides to remain in the service must take what amounts to a vow of celibacy. No married quarters are provided, and, if they were provided, the salary is totally inadequate for a married man. Next, with regard to hours of duty, the assistant medical officer is on duty twenty-four hours a day for seven days a week, with the exception of about two afternoons a week. If he requires a morning off he has to obtain the special permission of the medical superintendent, and the circumstances must be exceptional. If he is lucky he may obtain one or two week-ends in the year. I should like to add that no arrangements for post-graduate study are ever made, nor is any opportunity given to learn the administrative side of an asylum officer's duty. The work is mostly drudgery of a very uninteresting nature, and in the case of a man without influence the chances of promotion are almost nil.

Such are the realities of the asylum service as I have found them. I admit that in larger institutions the conditions are often better. Even in the smaller institutions in a few cases an enlightened administration has done much to alleviate the evils of a system which in other circumstances are well-nigh intolerable. But even in the most favourable circumstances I consider the position of an assistant medical officer in an asylum as poorly paid, unsecure, lacking in independence, and incomparably inferior to that of a general practitioner.

I suggest that the question of public posts in general, and that of asylum medical officers in particular, should be taken up with the local authorities by the British Medical Association. And here let me acknowledge with gratitude what has already been done by the Association. I shudder to think what would be the hapless plight of our profession if no such association existed. However, much remains to be done in the case of asylum medical officers. I make the following suggestions:

- 1 Security of tenure during satisfactory service with the setting up of some form of independent tribunal to decide questions involving professional conduct and discharge of duties.
- 2 Adequate remuneration with fixed scale of increment.
- 3 The provision of proper living accommodation with the opportunity to marry if desired.
- 4 Arrangements for post graduate study.
- 5 Reasonable amount of time off duty. Let me add in this connection that an attendant in an asylum gets two whole days off each week and three weeks holiday in the year. In many institutions the nurses work an eight-hour day with one whole day off in the week.
- 6 An adequate pension with compulsory retiring age of 55.

Until these points are settled in a satisfactory manner I strongly advise all young medical men to keep out of the asylum service.—I am, etc.,

October 1st

Obituary

HUGH FENTON, M A, M D,

Consulting Surgeon to the Chelsea Hospital for Women

We regret to record the death of Mr. Hugh Fenton, consulting surgeon to the Chelsea Hospital for Women which occurred on October 5th at his home in Herefordshire.

William Hugh Fenton was born at Shardlow in Derbyshire in 1854, his father being also a member of the medical profession and was educated at Derby School, from which he went to Merton College Oxford, and later to the London Hospital Medical School. He obtained honours in natural science in 1876 and a surgical scholarship in 1879, and qualified in 1880 with the diploma M R C S. Three years later he obtained the L R C P and graduated M D Briss.

In the first years after qualifying he took up diseases of the throat as a specialty, and actually became one of the physicians to the London Throat Hospital and surgeon to the Throat Hospital, Golden Square. His association with gynaecology began in 1883, when he was appointed anaesthetist to the Chelsea Hospital for Women and became private assistant to Dr. Palfrey, who was one of the fashionable gynaecologists of the time. This association of diseases of the throat and gynaecology will appear strange to the present generation, but in the days when both of these specialties were in their infancy it was by no means uncommon. When Palfrey died Fenton took over his house in Brook Street and settled down as a practising gynaecologist there, for in 1885 he had been elected assistant physician to the Chelsea Hospital for Women, gynaecology at that time being regarded as a province of medicine. Soon after his marriage in 1887 he removed to 27, George Street, Hanover Square, and in 1893 he became one of the full physicians to the hospital. A year or two later the institution was reconstituted, but certain members of the old honorary staff were reappointed, and among them was Fenton, who was placed on the senior staff, having as his colleagues the late Dr. William Duncan and Sir John (then Mr.) Bland Sutton.

From then onwards, till his retirement on account of age in 1914 he devoted his best energies to the welfare and advancement of the hospital. His professional work there will always be remembered by those who served with him for the conscientious way in which it was carried out, with the result that, without ostentation and in the most humble-minded spirit, he accomplished a record of surgical achievement of which any man might be proud. His skill as a diagnostician will perhaps remain most clearly in the minds of those who worked with him, he was certainly by far the most brilliant exponent of the art of vaginal examination that the writer has ever met. To posterity he will be known by two surgical instruments, the value of which has stood the test of time—Fenton's double-ended cervical dilators and Fenton's "bulldog" volsellum. But he was more than an able gynaecologist, he was a great practitioner, possessing beyond technical skill, that wider outlook—born of kindly understanding and ready sympathy—which raises one calling from a science to an art, and few medical men have been so beloved by their patients as he was. His services to the Chelsea Hospital for Women were very great, and the more so because they were given without stint at a time when the hospital most needed them. As a colleague he will be held in affectionate remembrance by all of us who had the good fortune to be associated with him. Entirely free from that petty jealousy which too often mars the character of able men, he held the work of his colleagues in generous appreciation. He was always kindly and helpful to every member of the staff from the lowest to the highest and was exceedingly generous to those under him.

In addition to the appointments mentioned above he served during the war as senior surgeon to the Hammer-smith War Hospital, and as surgeon to the County of London War Hospital at Epsom. He was also physician to the Society of Lady Journalists. In the British Gynaecological Society he had filled the offices of vice-president and honorary secretary.

Hugh Fenton was a keen sportsman and spent all his holidays fishing and shooting. The latter sport he had to give up by reason of advancing years, but the former

engaged him right up to the last year. The writer looks back with regret on many holidays spent with him in this delightful pastime, and rendered the more enjoyable by his cheery good nature and equable pleasantness. He married, in 1887, Alice Anne, eldest daughter of the late William Foster of Hornby Castle. His wife, who survives him, shared equally in the good work he did for the Chelsea Hospital for Women, and all his many friends will join in tendering to her their deepest sympathy.

V B

Dr. JOHN MALCOLM MACPHERSON, who died from pneumonia at Gorseinon, Glamorganshire, on October 4th, after a few days' illness, at the age of 39, had been engaged in practice in the Swansea district since the war. He received his medical education at the University of Glasgow, graduating M B, Ch B in 1912, in 1920 he obtained the D P H Wales. After qualifying he was for a time clinical clerk at the Woodilee Asylum, Glasgow, and in 1916 he removed to South Wales, where he ultimately settled down in practice at Gorseinon, near Swansea, holding also a number of part-time appointments, including those of medical officer of health for the Swansea Rural District and medical officer to the Swansea Union. He built up an extensive connexion and was a popular figure among his colleagues and with the general public. He was a member of the British Medical Association in the Swansea Division, whose members were well represented at the funeral on October 8th. We are indebted to Dr. W. A. MacLennan for the following appreciation. My memory of the late Dr. John Malcolm Macpherson goes back for nineteen years, to our student days at Glasgow University. The acquaintanceship formed there ripened into a warm friendship when, after the war, we found ourselves in adjacent practices. His death has caused universal regret. He was held in affectionate esteem by his professional brethren, and was loved by all classes. His was a most attractive personality, and his many noble qualities of heart and mind endeared him to a large circle of loyal friends. Of a generous nature he gave himself unstintingly in all he did. He had a keen and kindly insight into human nature, and this, coupled with his professional ability, helped him to maintain a large and successful practice. He was cut off with tragic suddenness in the flower of his manhood, and to us who were privileged to be his friends his untimely death has caused an irreparable loss.

Professor EDOUARD CHARLES ALBERT ROBIN, who died at Dijon on September 25th, was born there in 1847. After occupying the post of demonstrator in chemistry at the Faculty of Science of that city he went to Paris to study medicine, he qualified there in 1877, and won the silver medal for his inaugural thesis. He then became director of chemical research in the clinical laboratory of the Charité Hospital. In 1886 he was awarded the biennial Lœtze prize of 10,000 francs by the Faculty of Medicine for his "*Leçons de clinique et de thérapeutique médicales*," and in the next year was elected a member of the Académie de Médecine. Professor Robin was the first occupant of the chair of clinical therapeutics, founded about twenty years ago; he was also a Grand Officer of the Legion of Honour, president of honour of the international congresses of hydrology, climatology, and geology, president of the Société de Thérapeutique, and editor of the *Bulletin général de Thérapeutique* (1901) and of a *Traité de thérapeutique appliquée* (1895-97). He took an active part in the campaign against tuberculosis, and was the author of a book on the treatment of the disease which was translated into English in 1913. His principal work, however, was his monograph on diseases of the stomach, which reached a second edition in 1904.

The following well-known foreign medical men have recently died. Dr. OSKAR MENZ, professor of children's diseases at the Carohne Institute of Stockholm, whose name is associated with epidemic poliomyelitis, Professor JANOWSKI of Kiev, Dr. GUILLAUME ROSSIER, professor of obstetrics and gynaecology at Lausanne, Dr. W. MISTREZAT of the Institut Pasteur, Paris, and Professor C. A. LEE REED, a gynaecologist of Cincinnati, aged 74.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

At a congregation held on October 12th the following medical degrees were confirmed

MD—H G Hill
MB B Chm.—A W C Mellor T M Proctor G M Addison G H
Barendt C G E Plimstead D H Belfrage E T James T St. M.

* With distinction.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A QUARTERLY Council meeting was held on October 11th when the president, Sir Berkeley Moynihan, was in the chair. The diploma of Fellowship was granted to Robert Milnes Walker, and diplomas of Membership were granted to H T Flint H Joomyc and Marguerite C Rosser, who have now complied with the regulations. It was decided to purchase an opidiascope by Zeiss for the lecture theatre.

Mr H D Fleming was nominated as the thirty-sixth Jenks Scholar.

The draft copy of the annual report of the Council to be presented to the Fellows and Members at the annual meeting on Thursday, November 15th, was approved and adopted.

CALENDAR FOR 1928-29

The College Calendar for the current year besides much other information arranged on familiar lines includes a report of the proceedings of Council during the past twelve months. Full details are given of the scheme for holding in Canada the primary examination in anatomy and physiology for the Fellowship which has been arranged with the Canadian Medical Association and the Council is now in communication with the College of Surgeons of Australasia about the feasibility of a like arrangement for Australia.

The subject of the Jacksonian Prize essays for the year 1929 is 'The pathology, diagnosis, and surgical treatment of diseases of the salivary glands. The prize for 1927 has not been awarded.

In the period under review 76 diplomas of Fellowship were issued (including 2 to women), 676 diplomas of Membership (including 118 to women), and 100 licences in dental surgery (including 5 to women). The following diplomas were granted jointly with the Royal College of Physicians Public Health, 79 (including 24 women), Tropical Medicine and Hygiene, 77 (12 women), Ophthalmic Medicine and Surgery 39 (2 women), Psychological Medicine, 15 (2 women), Laryngology and Otology, 29 (1 woman).

The financial report shows that the total receipts in respect of current revenue during the year ending June 24th 1928 amounted to £27,939. The total expenditure of the College was £23,953. Receipts were £654 less than in the previous year, and expenses £708 more.

The Conservator's report opens with a full and appreciative account of the Strangways Collection and its history. This important group of preparations illustrative of rheumatoid changes in bone cartilage, and capsule was offered by the trustees of the collection—Sir Humphry Rolleston Professor H. R. Dean and Mr Malcolm Donaldson—to the Council of the College and was accepted in July. It has since been brought from Cambridge to the Museum, and after re-examination selected specimens will ultimately be incorporated as part of the Pathological Collection. Dr Strangways's name being attached to the description of each specimen and the valuable collection of microscopic preparations will be preserved as a special unit in the "Strangways Cabinet." The revision of this collection and the preparation of a descriptive catalogue have been undertaken by Mr R. Lawford Knaggs. Among gifts of outstanding value to the Museum Sir Arthur Keith mentions the presentation by Dr William Hunter to the College of his entire collection of specimens illustrating diseases of the blood-forming organs obtained from clinical cases which formed the basis of his classical inquiries into the causation and nature of pernicious anaemia. For this gift Dr Hunter has been accorded a special vote of thanks by the Council. The Odontological Department of the College has received from Sir James Berry a series of casts and models illustrating the methods he used and the results he obtained on cases of cleft palate treated by operation.

CONJOINT BOARD IN SCOTLAND

The following candidates have been approved at the examinations indicated

FINAL EXAMINATION—Medicine Y A R Ezziat W Stevenson
M G Lucas B Cunningham L H Abernethy Surgery Anna G

Medico-Legal.

EXPLOITATION OF SHAM FRACTURES

A motor engineer George Winter Williamson who pleaded guilty at the Mansion House, London, on October 11th, to two charges of fraud on an insurance company, was stated by Mr Percival Clarke, who prosecuted to have a congenital condition of the left clavicle which enabled him to simulate a fracture with ease, and so to have made twenty accident claims since 1922 obtaining £2,300 on nineteen of them. It was alleged that he had been living for years past on the proceeds of imaginary accidents. Williamson was charged with having by false pretences obtained from the Royal Insurance Company on June 15th a policy of insurance against accidents and on July 25th a cheque for £162, with intent to defraud. Mr Clarke said that the defendant in applying for the policy made a number of statements which were not true. He stated that he had no physical defect or infirmity, that he had good eyesight—though he had only one eye—that he had had no fractures or dislocations of bones and had never proposed for or made a claim in respect of any accident policy before. The policy in question had only been issued a few days when he made a claim in respect of a fractured clavicle a similar but unsuccessful fraud was simultaneously attempted on another insurance office. Mr J Albert Davis defending said that the accused's physical condition was not congenital but was really such as to render him especially liable to displacement of the shoulder blade and collar bone. Williamson was sentenced to six months imprisonment in the second division on each charge to run consecutively—twelve months in all.

The Services.

VOLUNTARY AID DETACHMENTS

The latest War Office returns of the progress made in the organization of voluntary aid detachments show that 90 men and 801 women's detachments comprising a total membership of 22,843 have received recognition under the scheme inaugurated in 1923. This is an increase of 40 detachments and 1,044 members on the previous half yearly returns. In all 3,834 members have taken the mobile obligation to serve in the event of a national emergency abroad or at home. Of the country areas London has a membership of 1,369 East Lancashire 1,170, and Norfolk 1,030 while Yorkshire (North Riding) Hampshire Yorkshire (West Riding) Somerset, Devonshire Surrey Cheshire Lincolnshire, West Lancashire Essex and Kent have each over 500 members. Scotland has a total membership of 3,418, the number of detachments being 123 and there are 49 Welsh detachments with a total membership of 1,310.

Medical News.

THE autumn dinner of the University of London Medical Graduates' Society, to which we referred in the *Journal* of September 29th (p. 584), will be held on Wednesday, October 31st, at 7.15 p.m., at the Langham Hotel Langham Place, W.1, with Sir St. Clair Thomson in the chair. Particulars may be obtained from the honorary secretaries of the society, 11, Chancery Street, W.1.

THE annual dinner of the Prince of Wales's Hospital Reunion Association will be held at the Trocadero Restaurant, Piccadilly Circus, on Thursday, November 8th, at 7.45 for 8 p.m., with Dr Charles Hadfield in the chair. Dinner tickets (12s 6d, exclusive of wine) may be obtained from Dr J. Browning Alexander, 42, Harley Street, W.1, or Dr S. O. Rashbrook, 7, Wellesley Road, Chiswick, W.4.

THE Birmingham and District Edinburgh University Club will hold its twenty-fourth annual dinner at the Queen's Hotel, Birmingham, on Thursday, November 8th, at 7.30 p.m., the Principal of the University of Edinburgh, Sir James Alfred Ewing K.C.B., LL.D., will be the guest of the evening, and Dr B. C. R. Aldren will preside. The club is open to all male graduates of the University, and it is hoped that any gentlemen who have not received notice of the dinner will communicate with the honorary secretary, Dr Ernest Bulmer, 87, Cornwall Street, Birmingham.

As already announced in our columns Dr Markusz Hajok, professor of oto-rhino-laryngology in the University of Vienna, will deliver the Semon Lecture on laryngo-rhinology and general medicine in the Barnes Hall, at 1, Wimpole Street, W, on Thursday, November 1st, at 5 p.m. The obit will be taken by Mr H. Bell Tawso, president of the Laryngological Section of the Royal Society of Medicine.

A CHADWICK Public Lecture on public health buildings and recent improvements in town developments in Sweden will be given by Mr Torben Grut, at the Royal Institute of British Architects, 9, Conduit Street, W 1, on Thursday, October 25th, at 5 p.m. Sir William J. Collins, K.C.V.O., M.D., chairman of the Chadwick Trustees, will preside. Admission is free.

THE annual special service for members of the medical profession and nurses in Sheffield and district will be held at the Cathedral, on Sunday, October 21st, at 3 p.m., when the Bishop of Sheffield will preach the sermon.

THE Fellowship of Medicine and Post Graduate Medical Association announces that the second lecture in the new series will be delivered by Mr E. G. Slesinger on Monday, October 22nd, at 5 o'clock, at the Medical Society of London, 11, Chandos Street, Cavendish Square, W 1, the subject being "Fractures at the wrist." On Tuesday, October 23rd, at 4 p.m., Dr C. G. Gledhill will give an x-ray demonstration at the Royal Northern Hospital, and at 2.30 p.m. on Friday, October 26th, there will be a clinical demonstration at the Cancer Hospital by Mr P. P. Cole. On Wednesday, October 24th, Dr Donald Hunter will give a lecture-demonstration on "Portals of entry in tuberculosis morbid anatomy and some clinical aspects" at the Wellcome Museum of Medical Science, 33, Gordon Street, W.C., at 4 p.m. All of these lectures and demonstrations are open to the medical profession, without fee. From October 23rd to November 10th the staff of the Hampstead General Hospital will give a special evening course, while from November 5th to December 1st a course in venereal diseases will be given at the London Lock Hospital. From November 12th until December 1st there will be a special course in ophthalmology at the Royal Westminster Ophthalmic Hospital's new building. A week's course in proctology begins at St. Mark's Hospital on November 12th, and from November 19th to December 15th there will be a late afternoon course at the West End Hospital for Nervous Diseases. From November 19th to December 1st there will be a special course at St. Peter's Hospital. Copies of all syllabuses and further information may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, London, W. 1.

A NEW course of post-graduate instruction in genito-urinary disease will commence at St. Paul's Hospital on Wednesday, October 24th, at 4.30 p.m., when Mr R. H. Jocelyn Swan will lecture on tuberculosis of the urinary organs. The lectures, which will be continued in succeeding weeks, terminate on December 6th, when Dr David Thomson will speak on common infection of the genito-urinary tract. No fee is charged for attendance. Medical practitioners and students are invited to attend any branch of the work in which they are interested. Tea is served at 4 p.m. Further information may be obtained from the secretary, St. Paul's Hospital, Endell Street, W.C. 2.

THE annual dinner of the Surgical Instrument Manufacturers' Association was held at the Holborn Restaurant on October 12th, under the chairmanship of Mr Patrick C. Maw, the new president. Mr A. W. Down, in testifying to the health of the association, said that it had now accomplished eleven years of useful work, and its membership included not only the heads of all the leading firms in the trade, but many other members of the craft, especially those expert in salesmanship and demonstration. Mr Maw, in reply, mentioned some of the activities of the association, and referred in grateful terms to the six years of devoted service by his predecessor in the chair, Mr E. W. Mayer. In response to the toast of "The Guests," Mr H. S. Souttar, F.R.C.S., said that the instrument maker was the right hand man of the surgeon, and the skill which the maker acquired in learning surgical needs was almost uncanny. In spite of the complexity of the instruments now produced, however, it was extraordinary how few of them were new. A little while ago a friend of his who had just invented a pair of gynaecological forceps, of which he was inordinately proud, was exploring the ruins of Herculaneum, and in the museum there found an exact anticipation, two thousand years old, of his own invention. Medical students, said the speaker, knew very little about instruments. He had had to examine students in surgery, and the most paralyzing part of the examination was when he showed the student an instrument and asked him what it was. It was pathetic to hand a student N. Macewen's osteotome and to be told that it was a chisel, the student evidently never having heard the name of Macewen. In hospitals such skilled assistance was at hand that the operation went through without the student

—sometimes without the surgeon—realizing how much was being done for him, though the surgeon learned this quickly enough when he went into the nursing home and had to find his own instruments and thread his own needles. Mr Souttar concluded by saying that he had an immense admiration for the British instrument maker. He had travelled a good deal on the Continent, and always made it a practice to see what other people were doing. Some times he picked up an instrument as a keepsake, but very usually that remained its only function. Generally one could get the same type of instrument in this country as abroad, and probably a much better one. Mr L. Ferris Scott added a few words of appreciation of the hospitality shown to the guests, and spoke of the admirable way in which the instrument-makers supported the annual exhibitions of the British Medical Association.

THE half yearly meeting of the British Spas Federation, at which were present representatives from Bath, Buxton, Cheltenham, Droitwich, Harrogate, Leamington, Llandrindod Wells, Strathpeffer, Trefriw Wells, Woodhall Spa, and New Zealand, was held in London on October 3rd. Lengthy discussions took place regarding foreign competition, and various methods were suggested for overcoming the present practice of many British people of going to foreign spas, although at British spas the facilities for treatment, the methods of giving treatment by a medically trained and fully qualified staff, and the amenities of the spas were at least equal to those prevailing at foreign spas. The federation proposes shortly to publish in book form the results of the research work which has been carried on intensively at British spas during the last few years by various medical committees and chemists.

MR SAMUEL P. COOPER of Moseley, Birmingham, who died in June last, has bequeathed £1,000 each to the General Hospital, Birmingham, the Queen's Hospital, Birmingham, and the Birmingham and Midland Free Hospital for Sick Children, and to Dr Barnardo's Homes, £500 each to the Birmingham and Midland Eye Hospital and the Birmingham and Midland Homoeopathic Hospital, and also to the Children's Hospital at Cold Ash, Newbury, if his niece is matron there. After other bequests the residue of the property is to be divided between the General Hospital, the Queen's Hospital, the Birmingham and Midland Free Hospital for Children, and Dr Barnardo's Homes. Under the will of the late Mrs Emily Crossley the Ancoats Hospital receives £2,000.

MR HENRY KIMPTON announces for early publication a second edition of Kellogg Speed's *Text book of Fractures and Dislocations*, in one volume of 952 pages, with 987 engravings.

THE October issue of *Leprosy Notes*, which is the quarterly publication of the British Empire Leprosy Relief Association, contains numerous articles of special interest. Dr A. B. Macdonald describes the founding of a leper colony in Nigeria, Dr J. O. Shircore supplies a short note on leprosy work in Tanganyika, Dr F. O. Birkenstock gives a general account of a Central African treatment centre, and Dr N. Macvicar reports on a visit to the Government Leprosy Institution at Enjanyana in the Transkei. The Rev G. M. and Mrs Kerr record the progress made since 1916 at the Dichpall Leprosy Hospital in Hyderabad, and a note on the campaign in Bengal is contributed by Dr E. Muir. Sir Leonard Rogers writes on the progress of modern prophylaxis, and Dr R. G. Cochrane reviews the present-day methods of the treatment of leprosy. Other articles deal with work in the Gold Coast Colony and the part played by nursing in leprosy. This useful publication can be obtained from the secretary at the office of the Leprosy Relief Association, 24, Cavendish Square, W. 1.

COLONEL ASTLEY V. CLARKE, M.D., J.P., has been appointed deputy lieutenant for the county of Leicester.

DR J. BEE of Bromley and Dr W. C. Milles of Cubitt Town have been appointed justices of the peace for the county of London.

A BELGIAN league against rheumatism has recently been founded under the presidency of Professor H. Verhoogen. Its object is the social and scientific study of rheumatism and its treatment in institutions in Belgium and abroad sanctioned by the league.

A CHAIR for industrial hygiene has been founded at the Naples Faculty of Medicine with Professor Nicolo Castellino as its first occupant.

A CONFERENCE of the German Association for Combating Rheumatism will be held in Berlin, from November 4th to 7th. Demonstrations will be given in different Berlin clinics. Further information may be obtained from Dr D. Hirsch, the general secretary of the conference, Traunhoferstrasse 16, Charlottenburg, Germany.

A POST GRADUATE course in diseases of children will be held in Vienna from November 26th to December 8th. Details may be obtained from Dr A. Kronfeld, Porzellangasse 22, Vienna IX.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W C 1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the **British Medical Journal** alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the **British Medical Journal** must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W C 1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the **Journal**, should be addressed to the Financial Secretary and Business Manager.

The TELEPHONE NUMBERS of the British Medical Association and the **British Medical Journal** are **MUSEUM 9561 9562, 9563, and 9564** (internal exchange four lines).

The TELEGRAPHIC ADDRESSES are

EDITOR of the **British Medical Journal**, *Aitology Westcott*
London

FINANCIAL SECRETARY AND BUSINESS MANAGER
(Advertisements etc.) *Articulate Westcott*, London

MEDICAL SECRETARY *Mediscrea Westcott*, London

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus*, Dublin) telephone 62550 (Dublin) and of the Scottish Office, 7 Drumshugh Gardens, Edinburgh (telegrams *Associate*, Edinburgh), telephone 24361 (Edinburgh).

QUERIES AND ANSWERS

TREATMENT OF CHRONIC URTICARIA

"INQUIRE" asks Could any reader suggest treatment for a man aged 28 who has urticaria, from which he is never entirely free, and at times suffers from acute attacks. No particular sensitizing agent has been found.

SALICIN ADMINISTRATION IN PREGNANCY

"H. C." asks whether the large doses of salicin advocated in influenza by Mr. Turner and others can be quite safely used at any stage of pregnancy without risk of miscarriage or injury to the foetus.

HYPERTRICHOSIS

"C. S." writes One of my patients, a girl of 19, is much concerned because of a thick growth of hair on her arms and legs, and has consulted me about the possibility of removing this unsightly fur. I should be glad of advice.

*. A dermatologist, to whom we have referred the question, replies This is essentially a case for a depilatory. It can be made by the medical man himself by drying freshly precipitated barium sulphide, but in all probability it will be found more satisfactory to use one of the many proprietary preparations on the market. This is the legitimate field for their employment.

WANTED—A HOME

"T. R. C. S." writes I am anxious to get in touch with a doctor on the south coast of England who would be prepared to take into his home a girl of 10½ for the winter months. She has had serious osteomyelitis of the ilium, with infection of the hip joint. She is herself the daughter of a doctor abroad. She will be able to get about to some extent but will want a good deal of special care. Some provision for education either in the home or within reach is desirable, preferably with other children. But the most essential point is a good sunny, healthy site and plenty of open air facilities.

CORNS

DR P. CLENNELL FENWICK (Christchurch, New Zealand) who is in charge of the radium and deep therapy department of North Canterbury Hospital, writes With reference to the query of "H. A. A." on July 14th (p. 85), I suggest that he should try the effect of soft x rays on corns. We have treated a number of cases in this department with pleasing success. Our dosage is kilovolts, 150, filter, 1 mm. of aluminium, distance 50 cm. time to give a Babouard pastille dose 4½ minutes. The foot is shielded with thin lead, with a hole out to expose the corn. We avoid raying any part except the actual corn, since we find the tissues of the foot react very quickly to x rays. We give one dose, repeated in ten days, and a third dose ten days after the second. We find that the patient loses the pain very quickly after the first dose, that after the second application the hard area is softened, and after the third dose there is distinct softening and lessening of the whole area. I think this treatment is well worth a trial, since, in my own case I found relief from a very painful corn on the foot (caused by ill-fitting military boots), which had resisted all forms of treatment for some years.

INCOME TAX

Replacement of Car

"J. D. L." bought a car A in 1921 for £700 and car B in 1922 for £150 using both in his practice. In 1927 car C was bought for £400 and car B (value, say, £10) ceased to be used.

*. The Inspector of taxes regards C as replacing B, "J. D. L.'s" view is that C has replaced A and A has replaced B. Replacement consists of the purchase of one asset in place of another, normally the one discarded is sold, and it is not arguable that in such circumstances any other is involved. In this case the fact that car B is still retained (though not used) complicates the matter somewhat, but the same principle applies, and we are of opinion that the inspector's view is correct. The question is not one of replacement in the sense of one car being used instead of another, but of replacement as an asset of the practice.

LETTERS, NOTES, ETC.

AN OVERDOSE OF MEDNAL

"LOWLAND DOCTOR" sends the following note on the effects of an overdose of mednal. A tabetic patient (he writes) a woman aged 48 who suffers severely from gastric crises and lightning pains in the legs, has been undergoing treatment with bismuth preparations for the past year. She suffers also from menopausal symptoms associated with a systolic blood pressure of 165 mm. Hg. The pupils are always irregularly dilated. For the past year or so she had been accustomed to take one half to three-quarters of a 7.5-grain tablet of mednal when the pain was very severe. On September 23rd she went to bed in the afternoon complaining of severe pain. Next morning I was called in to find her comatose with stertorous breathing. Paralysis was complete and there had been retention of urine for twenty-four hours. Her previous high blood pressure and irregular pupils made diagnosis difficult. Since the relations had no tally of the tablets taken I treated her at first as a case of cerebral haemorrhage. As time passed I felt more confident that she was suffering from an overdose of mednal, at length after vigorous stimulation and shaking, she opened her eyes—forty-eight hours from the time of taking the tablets. It was the fourth day before she was able to form a word or recognize her relations, although her hearing seemed acute. By the sixth day she was able to tell me, in a hesitating manner, that she had taken nine tablets as the pain was so bad. Now at this end of eleven days she is mentally alert but physically very weak. The retention of urine lasted five days.

MEDICAL GOLF

THE autumn meeting of the Medical Golfing Society was held at Princes Golf Club, Sandwich, on October 13th and 14th, by kind permission. The course was in excellent condition. Special thanks are due to Captain Baird the secretary of the club. The results of the competitions were as follows:

Singles v. Bogey (for Dr. Bathurst prize)—1st T. A. Torrance 2 up
2nd N. C. Carver (after a tie at 2 up each)
Foursums v. Bogey (for Mr. Max Page's prize)—1st A. C. Carver
and G. Hebert (after a tie with T. A. Torrance and Mr. Kenneth Goodby at 2 down each)
The Gannu Ryall Cup—1st J. D. Gray 75 (92-16) 2nd A. Galletly 77 (82-5) 3rd J. W. Yorke Davies 78 (96-18)

MONTONE HOME OF REST

WE are asked to direct attention once more to the fact that professional men of limited means who require a change are received into the Home of Rest at Montone at a charge of 30s a week for board and lodging. Special consideration may be given to the cases of those who cannot pay this amount. The stay of each person is limited to three months. The homes are open from November 1st to May 1st. It is a philanthropic undertaking, designed to help professional men who break down temporarily, and is therefore useful to medical practitioners of small means, or their professional patients similarly situated. Further information may be obtained from the lady superintendent, or the honorary physicians Dr. D. W. Sawways and Dr. Stanley Rendall, at Montone, Alpes Maritimes, France.

A CHOCOLATE BICENTENARY

THE bicentenary number of *Fry's Works Magazine*, issued to celebrate the 200th anniversary of the entrance into business in this sphere of Joseph Fry, the founder of the well known firm of Messrs. J. S. Fry and Sons chocolate and cocoa manufacturers, contains an interesting account of the development of this huge concern richly illustrated with photographs and sketches. As mentioned in the *Journal* of July 28th (p. 182) Joseph Fry was a medical practitioner in addition to his association with the manufacture of chocolate, he was a partner in a oilon works and a soap-making business, the owner of a chemical works, and the originator of a type foundry. Lord Riddell writes in the *Magazine* on "The chocolate age", Mr. Ernest Bevin, in an article on "The growth of trade unionism," pays a tribute to the working conditions and the satisfactory relations prevailing between employers and employed in the firm's establishments, and Mr. Charles Wells contributes an account of "Bristol in 1728."

VACANCIES

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals will be found at pages 44, 45, 48, 49 and 50 of our advertisement columns, and advertisements as to partnerships, assistantships and locum tenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the *Supplement* at page 171.

Remarks

ON

THE TEACHING OF HYGIENE.*

BY

W. W. JAMESON, M.A., M.D., M.R.C.P., D.P.H.,
Barrister-at-Law, Professor-designate of Public Health, London
School of Hygiene and Tropical Medicine

ALL practitioners of medicine must of necessity be doctors or teachers as well as healers of the sick, and I can think of no subject more likely to arouse general interest than that chosen by the officers of the Public Health Section for discussion to-day. It was originally intended that three speakers should open the discussion—one dealing with the training of health workers, another with the teaching of hygiene to school children, and a third with public education in health. Unforeseen circumstances have unfortunately made it necessary for me to introduce to your notice all three aspects of the question. I shall endeavour to deal mainly with principles and leave the discussion of details to subsequent speakers.

THE TRAINING OF HEALTH WORKERS

Of recent developments in connexion with post-graduate public health teaching I propose to say nothing, and I shall rather confine my remarks to the teaching of preventive medicine to medical students and to the training of certain members of the subordinate health services.

Medical Students

Let me say first of all that there is no more important person in the ranks of health workers than the general practitioner of medicine. He can do much to make or to mar any effort put forward by the more specialized public health service, and if the greatest measure of success is to attend our work the general practitioner must understand our aims and must fit into each of our schemes. To enable him to do this he must be given a correct sense of proportion when a medical student. You will recollect that in the revised medical curriculum of the General Medical Council it is laid down that the subjects of hygiene and public health should be included in every course of professional study and examination, and that courses of instruction in these subjects should be taken concurrently with the later stages of clinical instruction. The Council further resolved that throughout the whole period of study the attention of the student should be directed by his teachers to the importance of the preventive aspects of medicine. I am never quite clear in my mind as to where hygiene ends and public health begins, and, so far as medical students are concerned, I would rather refer to the whole subject as preventive medicine. Such a title makes a more definite appeal to the average medical student, and every effort to capture his interest is worth making. Great differences exist between the courses of instruction in preventive medicine given in the various medical schools, both in regard to the number of lectures (and, may I add, the payments made to the lecturers) and in regard to the subjects discussed. In certain schools, mainly in London, ten or a dozen lectures seem all that can be included in the curriculum, whereas in the provincial universities twenty, thirty, or even more lectures may be given. This is probably due to the fact that the provincial medical officer of health has usually a much greater influence on the policy of his local medical school than is possible in the case of his metropolitan confrere. Then it is the practice in certain schools to devote a considerable amount of time to lectures on general sanitation and to demonstrations on water purification, sewage disposal, sanitary appliances, and the like, in other schools but little attention is paid to this aspect of the question. Variety in the method of presentation of a subject is always to be commended, but preventive

medicine is so vast and so important a study that some discrimination must be exercised in the selection of the material to be presented to the medical student, more particularly in view of the already crowded state of the medical curriculum. It may or may not be the case that the various teachers act on the advice of the General Medical Council and endeavour to keep before the notice of the student the importance of the preventive aspects of medicine, in any event it is at least convenient that one lecturer should touch upon the various subjects of the curriculum and lay stress in each case on methods of prevention. Preventive medicine ranges over many fields and can have no recognized limits as have certain of the other subjects taught in our medical schools. To my way of thinking a lecturer in preventive medicine achieves his object if he succeeds in arousing the interest of his class and in giving them a definite preventive point of view. He cannot turn medical students into medical officers of health by forcing them to attend a short course of lectures, but he can see to it that every young man or woman starting in practice is aware not only of the principles of prevention, but also of his own function as a practitioner of prevention. The student must be shown the place of the practitioner in relation to the various schemes organized and maintained by local authorities all over the country, and he must be taught the important influence of environment upon health. If these matters are not placed clearly before him he will leave his medical school after acquiring knowledge in the dissecting room, the laboratory, the hospital ward, and the out-patient department, and he will think in terms of these, to his own and to the nation's future detriment.

A course of lectures on preventive medicine should be given in the final year of the medical curriculum and should deal among other matters with the triumphs and failures of prevention with an outline of public health administration in this country with the chief sources of statistical information and with the importance of correct certification and notification, with all the various organized schemes of prevention in existence and with the special measures available in connexion with the principal groups of diseases with the importance of pure air, pure water and pure food (this includes a good deal of personal hygiene), and with the evil effects of bad housing and insanitary conditions generally. Throughout the whole course the part the student himself will have to play and the ways in which difficulties may be avoided or overcome must be kept constantly before his notice. In my judgement lectures dealing with details of constructional work and with complicated processes of ventilation, water purification, sewage disposal, and similar problems only confuse the student and make him feel he is being forced to listen to something which is really the business of experts and which will have only an indirect bearing on his future practice and I am not inclined to disagree with him. A course of lectures on the lines of Sir George Newman's *Outline of the Practice of Preventive Medicine* seems to me particularly well suited to medical students and I always recommend that little book to them for their careful perusal.

It might be well if lecturers on preventive medicine could agree on a definite syllabus of instruction for use in our medical schools, and it would also be helpful if the printed requirements relating to hygiene of some of the examining bodies were to undergo revision in the near future.

Sanitary Inspectors

To meet the wishes of the Minister of Health the bodies whose certificates were recognized by the Sanitary Officers Order, 1922, have been combined under the title of the Royal Sanitary Institute and Sanitary Inspectors' Examination Joint Board. The object of the Board, which commenced examining in 1926, is to provide a uniform system for the examination and certification of persons seeking appointment as sanitary inspectors in England and Wales. Before a candidate is accepted by the Board he must have passed one of a list of approved examinations, of which the matriculation examination of London University and the preliminary examination of the National Association of Local Government Officers are examples, or must produce evidence of having acquired such general and technical knowledge as may be approved by the Board. It was felt necessary, when the Board began its work to raise the standard of general education for entrants to the inspectorate, and many interested persons feared that the insistence placed on general education might tend to produce candidates whose main training had been

* A paper read in opening a discussion in the Section of Public Health at the Annual Meeting of the British Medical Association Cardiff 1922.

obtained in the clerical division of a public health department and to keep out candidates who had served their apprenticeship in one or other of the building trades. Nothing in my opinion would be more fatal to the standing of inspectors than such a state of affairs. The ability to draft a good report may be necessary, but the capacity to meet a builder on his own ground and to discuss technicalities with him in such a way as to make it evident that the inspector has himself been a craftsman is of still greater importance, and I am glad that the Board has interpreted this preliminary examination qualification in a broad-minded way.

The actual training demanded of candidates includes attendance at a six months' part-time course of lectures and demonstrations based on a comprehensive syllabus of subjects. The course must be held at one of the approved institutions, of which there are three in London, ten in the provinces and one in Scotland. In addition candidates must have undergone practical training in the duties of a sanitary inspector as a rule, for a period of one year, some reduction in time being made in the case of men who have had at least three years' practical experience in one or other of the building crafts. The standards of training and examination are high and the Board has become a body in which the public health service has complete confidence. A most necessary qualification for most sanitary inspectors is the certificate of "Inspector of meat and other foods" granted by the Royal Sanitary Institute. Candidates, who must as a general rule hold the certificate of sanitary inspector, must produce evidence of having attended for at least two months an approved course of lectures and demonstrations (there are two such courses in London and eight in the provinces) including training in meat inspection at a cattle market and slaughtering establishment recognized by the Institute. The examination is of high standard and every candidate has to display a very considerable amount of practical knowledge before he can obtain the certificate.

Health Visitors

During recent years the training of health visitors has been the subject of much discussion, and the conditions of entry to the service are now more or less standardized. All women appointed as health visitors for the first time after April 1st, 1928, must hold the Health Visitors' Certificate issued by the Royal Sanitary Institute with the approval of the Minister of Health.

The examination qualifying for this certificate is open (1) to nurses who have completed a three years' course of training either at a recognized general hospital or a recognized children's hospital, who have obtained the certificate of the Central Midwives Board and who have attended an approved whole-time course in public health work lasting for at least six months and (2) to women not being trained nurses who have undergone an approved course of training in public health work for two years, together with six months' training in hospital and who have obtained the certificate of the Central Midwives Board. It will be noticed that all new entrants to the service, whether trained nurses or not, must take a whole-time course of instruction. There are eleven institutions—five in London and six in the provinces—where such courses are obtainable and in all cases arrangements are made for practical training at maternity and child welfare centres and similar places to accompany the more theoretical lectures. The examination for the certificate which consists of three written papers and an oral examination is of a searching character.

It may be of interest to contrast a similar course given in the Institute of Public Health of the University of Western Ontario. There the certificate of Public Health Nurse is granted, after examination, only to candidates who have taken a course consisting of lectures, demonstrations, clinics, laboratory work, and field work occupying one academic year of about nine hundred hours—thirty hours a week, from September to May inclusive. About one-half of the total number of hours is devoted to practical field work under instructors professionally engaged in public health work in the town of London, Ontario. Students may apparently spread the work over two or three years, and need not then attend full-time. The course is open only to trained nurses showing a satisfactory standard of general education.

Much argument has raged round the question as to whether or not only trained nurses should be accepted as candidates for the health visitors' examination. The bulk of opinion is in favour of such training, but the Minister of Health, in deference to the wishes of certain of the teaching institutions, has retained the two years' whole-time course for persons without nursing training. May I say that some of the best health visitors I have encountered possessed no extended nursing training, but they

were, of course, doing only maternity and child welfare work. It is probably just as well to retain both types of entrant to the service.

Some anxiety has been felt lest these new conditions should result in a dearth of health visitors. In my opinion the conditions are not a bit too exacting for persons entering the responsible office of health visitor, but it is certain that few women will be prepared to expend the money necessary to obtain whole-time courses of training so long as the salaries of health visitors remain at their present ridiculously low level. A service must be made attractive if a good type of entrant is to be got, and I can see no adequate reason why a local authority should not pay their health visitors as good salaries as are paid to the women teachers on the staffs of their public elementary schools. In a recent circular the Minister of Health has indicated to local authorities two ways in which intending health visitors may be helped to obtain their training. The first suggestion is that, in areas where an ordinary full-time course of training lasting six months has been provided, candidates, who undertake to serve as health visitors in these areas for at least six months after obtaining the health visitor's certificate, may receive from the local authority during their training an advance of salary, to be repaid in the course of the first six months' period of service as health visitor. The other suggestion deals with the employment of probationer health visitors. In this case the course of training must extend over not less than three academic terms, and may be arranged, for example, jointly by a local authority and a university. Probationers must be trained nurses holding the certificate of the Central Midwives Board. Such a scheme is, I understand, in force in the county of Durham, and is meeting with a considerable amount of success. It is interesting to note that a similar procedure has been suggested in the case of New South Wales. There the proposal was to appoint women as cadet nurses during their course of training, such cadets to sign a bond agreeing to serve as health visitors for two or three years after completing their course.

Midwives

Most of us are aware that pupil midwives, other than trained nurses, have to undergo training for a period of one year before they are allowed to sit for the certificate of the Central Midwives Board. In the case of trained nurses the period of special training lasts for six months.

Pupils must be certified as having examined and received instruction in the supervision of not less than twenty pregnant women, and it is suggested that attendance at ante-natal clinics affords excellent opportunities for instruction of this nature. It is now necessary that ten labours should be witnessed, that the first five cases personally delivered must be attended in an institution approved by the Central Midwives Board and that of the remaining fifteen at least five must be attended in the patients' own homes. The object of this is to ensure that the pupil first learns the methods of surgical cleanliness under the easiest and best possible conditions, and afterwards extends her education by attending and nursing outdoor cases so that she may also learn how to apply hospital methods to the more difficult circumstances of the patients' homes and how to improvise and make the best of what she finds there. Such experience will indicate to her her relations with and duties to the local health authority and the need for co-operation with private medical practitioners and voluntary and other agencies for the assistance of mothers and babies. The number of lectures a pupil has now to attend is thirty and the minimal period over which they are spread is four months.

It must be remembered that in spite of the recent efforts of the Central Midwives Board our training courses are still much shorter, and perhaps less thorough, than those in operation in other European countries, notably Holland and Denmark.

Dame Janet Campbell's comments on the training of midwives contained in her last report, *The Protection of Motherhood*, 1927, are interesting, and might well be discussed by this section. She points out that no discrimination is made between the pupil who intends to practise midwifery and one who merely desires the additional qualification of the certificate of the Central Midwives Board. Thus a nurse who has no intention of practising may enter one of the best-equipped training schools while the woman who intends to practise, and therefore needs the widest experience possible, may be driven to a small

institution where the facilities are limited and the teaching is often not of the highest quality. It is of interest that only 22.7 per cent of midwives on the roll in March, 1927, were in practice in 1926. Again, the amount of maternal for teaching purposes is becoming steadily less, and is likely to diminish still further in the future. These considerations have led Dame Janet Campbell to suggest

1 That there should be two classes of midwifery certificates—(a) for the practising midwife whose training cannot be too good or too thorough and (b) for the 'obstetric nurse' who desires some knowledge of midwifery for work in hospital in the public health service and in private nursing but who does not intend to practise as a midwife. (This class of certificate would be obtainable only by a trained nurse.)

2 That midwifery schools should be classified and that only those schools which can offer a full and complete training should be allowed to accept pupils for training as practising midwives.

The possibility of increasing the period of training to eighteen months or two years and of including within the period practice under supervision after the examination has been taken but before the certificate has been granted is also suggested.

All these ideas appear likely to give rise to considerable discussion.

Fever Nursing Certificate

Those of us who have charge of modern, well equipped isolation hospitals know that a very fair degree of nursing skill can be obtained by women trained in such institutions. Much of the work is of an acute nature, most of the patients are young children and the experience gained in the handling of infectious persons is a very valuable one. I regard some isolation hospital training as highly important in the case of the nursing staff of a public health department. You will recollect that the preliminary examination of the General Nursing Council is the same for all nurses, whether from general hospitals or from isolation hospitals.

In a complete training school for fever nurses this examination may be taken at the end of the first twelve months and the final examination at the end of two years. Many isolation hospitals are not regarded as having sufficient material to afford a complete training and these with the consent of the General Nursing Council may become affiliated to complete training schools provided that the whole period of training is not less than two years and six months of which not less than one year must be spent at the latter institution. The preliminary examination must be passed before the nurse enters the complete training school from an affiliated school. This arrangement is I suppose the best that can be made but it operates a little harshly on the smaller hospital for as soon as a probationer there begins to be really useful she is transferred to the larger institution. The erection of small isolation hospitals though a measure to be deprecated is not altogether avoidable especially in rural areas and the staffing of such places always presents a good deal of difficulty. The rules of the General Nursing Council provide for a four years course of training for those nurses who having spent two years at a complete training school for fever nurses, and having passed the final examination proceed to a general training school. This means that training in a general hospital in such cases may be reduced by one year but only in very few instances has such an arrangement been made.

It seems rather ridiculous that a woman who has passed the preliminary examination common to all nurses in training, as well as her final examination for fever nursing, should be compelled to enter a general hospital on the same basis as a woman who has had no previous hospital training whatever.

I fear I have occupied too much of the time allotted to me in discussing the training of health workers, but my excuse is twofold. First, this was the subject I was asked to deal with in the first instance, the other heads of discussion having since been thrust upon me and in the second place no educational scheme can be successful without a nucleus of well-trained and intelligent officials. Health education must of necessity be guided by members of the medical profession and by the staffs of public health departments.

HEALTH EDUCATION IN SCHOOLS

It is not necessary for me to remind an audience such as this that the training of a child in the formation of health habits must begin with its earliest days. I might almost say hours. The lack of any such training is seen only

too often in the infant departments of our elementary schools. That an improvement is gradually being effected is due largely to the efforts of our maternity and child welfare workers. When a child first goes to school at the age of five it is more easily influenced by the school environment than at any other period of its school life. For a moment the school becomes predominant and in many cases home becomes almost a factor of secondary importance. As the years pass the child is apt to be influenced more by what it sees and hears at home and in the streets hence it is of the greatest importance that its health education should be commenced in its first school years and that the practice of hygiene should be made so far as possible a matter of habit. If the child is to be well taught the teacher must understand her subject and be able to present it to the class in an attractive manner. The proper person to give instruction in hygiene to school children is the class teacher, and not a special teacher. We want to prevent the child from getting the idea that hygiene is anything but an everyday routine, and to let the child think for one moment that its own teacher is unable to handle the subject would be fatal. I mention this because I have been told more than once that the most suitable person to teach children hygiene is the school medical officer. Now the inculcation of good habits and the teaching of hygiene are not the simplest of matters, and I venture to suggest that insufficient attention is paid to this subject in many of our training colleges. In these institutions lectures on hygiene should be given by specially qualified men and women, and no effort should be spared to make students appreciate the importance of the subject and the great results that may be achieved by its intelligent and unremitting practice in all schools.

All of us must welcome the prominence given to this aspect of health education by Sir George Newman during the past year or two, and we must regard as most timely the appearance of the Board of Education's *Handbook of Suggestions on Health Education* intended for the consideration of teachers and others concerned in the work of public elementary schools. In his introduction to the handbook, Sir George Newman lays stress on a number of highly important points. He emphasizes the fact that hygiene is so essential that it can never be merely a "subject" of instruction, but must enter into the total life and experience of the child. Indeed, the Board considers that the physical health and condition of the child are the basis upon which all mental education must necessarily be founded, and it regards the importance of hygiene and physical training, like that of moral training, as being so great that no one would propose their omission from the curriculum of any elementary school. Sir George Newman points out that there are three principal ways in which health may be both acquired and taught in youth: (a) by habit-training, (b) by learning the truths of biology, chemistry, and physics, and (c) by understanding the principles and practice of good living itself. In a young child under 10 or 11 years of age hygiene should be taught as a rule by habit-training. Daily health exercises should be carried out by such children, and five or ten minutes a day may very well be spent in this fashion. The methods adopted will vary with individual teachers, but such matters as the importance of cleanliness and of fresh air and the care of the teeth must be so drilled into the children that their practical application will become entirely a habit.

It should be remembered that the health of a nation is in a large degree dependent upon the habits of the people and what they need in order to live well is not abstruse knowledge but to practise the knowledge they possess already. Most people know a good deal about the value of cleanliness, fresh air and ample food but they do not always practise what they know. They have not in youth contracted the habit of doing so.

In the case of children over 11 years of age instruction may be given under the heading of "hygiene" or it may be included in the general science course or form part of nature study. The older girls will naturally get a good deal of instruction in hygiene in their domestic subjects course. In any event a definite amount of ground should be covered in each term and the work should be carefully planned out beforehand. That it can be done successfully

is seen by what has been carried out in my own borough since 1904. In that year a syllabus of instruction in hygiene was issued by the Education Committee—it was drawn up, may I say, by the present Chairman of Council of the British Medical Association—and since then, with few exceptions, has been followed conscientiously in all our elementary schools. The syllabus has required but little alteration in recent years to bring it completely up to date. The question of permitting teachers to give instruction on matters relating to sex came up for consideration in connexion with the revision of the syllabus last year, and it was felt that to authorize all teachers to give instruction of this nature would be a mistake. The difficulty was got over by issuing a printed letter, addressed to head teachers and accompanying the syllabus, authorizing them to deal with this aspect of hygiene as they thought necessary or desirable.

The kind of health education in schools most likely to be of permanent benefit is that undertaken by the teaching staff, aided on all possible occasions by the school medical service. The visits of the school medical officers and of the school nurses should be regarded as illustrating the lessons on hygiene and should be made as much a part of the school curriculum as possible. Assistance can often be given by the school medical service in the selection of suitable posters and pictures and in the compilation of booklets and pamphlets for distribution amongst the scholars. Special efforts such as are made during health weeks and in competitions of various sorts have their uses, but it is the daily routine that counts most in the long run.

PUBLIC EDUCATION IN HEALTH

Attempts to instruct the public in matters affecting health are not of recent origin. They date at all events from the days when the Mosaic code, that wonderful syllabus of hygiene, was taught to the children of Israel. It was not, however, so far as I know, till the beginning of last century that active societies began to be formed in this country for the express purpose of educating the public. A "Health of Towns Association" was one of the first in the field, and in 1846 a "Health of London Association" was formed with the object of "instructing the people as to the evils which result from the present defective sewerage, drainage, ventilation, street cleansing, and supply of water, from interment in towns, and from other sources of injury to the public health, and of showing the beneficial influence which the removal of these evils would certainly exert on their physical and moral condition." Efforts in those days were directed mainly towards an enlightened public opinion among the middle classes, whereas modern propagandists make their appeal to all and sundry, regardless of class. After 1870 societies, institutes, and associations began to multiply to a very considerable extent while the past twenty years have been the most prolific period of all. At the present time there are over fifty bodies engaged directly in this class of work.

As would be expected in this country, the foundations of a scheme of public education in health were laid by voluntary effort, and we owe a great debt of gratitude to the pioneers. The date of official entry into the field may be taken as 1911, when the National Health Insurance Act gave Insurance Committees power to arrange for the giving of lectures and the publication of information on questions relating to health. Later, local authorities were enabled to undertake educational work of a special nature under the Tuberculosis Regulations of 1912, the Venereal Diseases Regulations of 1916, and the Maternity and Child Welfare Regulations of 1918, and were given much wider powers (at any rate outside London) by the Public Health Act of 1925. It is thus obvious that an enormous amount of effort, both voluntary and official, is capable of being aroused.

In my way of thinking the most valuable kind of health education is that being undertaken day in day out in a well-conducted sanitary area where the staff is competent and reasonably sufficient. The visits paid and the advice given by intelligent and courteous sanitary inspectors,

health visitors, and school nurses, combined with well-administered schemes of maternity and child welfare work, school medical inspection and treatment, anti-tuberculosis work, and the like, are the finest means of teaching the public we possess. The medical officer of health who neglects perfecting these services and aims rather at more showy special measures is building upon sand. We must of course, make different appeals in different types of area, but a striving after the sensational is likely to do more harm than good. No one has a greater opportunity for the dissemination of health knowledge amongst the public than the general practitioner. Were he to regard himself as primarily a teacher much could be accomplished, and there is need for the public to be educated up to this ideal of medical practice. I am glad to see that the Industrial Health Education Society, one of the most recent, and certainly one of the most active, of our voluntary societies, has induced general practitioners all over the country to give lectures to groups of workpeople drawn from the various trades. The results have been most successful, and the annual report for 1927 states that

"the rapid growth of the society bears witness to the fact that the workers are very interested in matters of health and are desirous of knowing how to prevent or at least to mitigate the sicknesses and diseases incidental to their occupation. In fact the workers are realizing that health is an inheritance and that though they can spend the interest in work and play they must not break into the principal."

Now this business of health education—for it has almost become a business—is sorely in need of some organization, or at any rate of some co-ordination. This has been felt by no one more than the medical officer of health, and it is with a view to getting some sort of order out of the chaos that exists that the Central Council for Health Education has been formed. This council, which is composed of representatives of local authorities of all sorts and of medical officers of health, is intended to act as a sort of clearing-house and co-ordinating centre for all kinds of health propaganda. The council knows where the best material for any class of work connected with health education may be obtained, and upon what terms. It is compiling lists of approved lecturers, films, lantern slides, posters, pamphlets, and all the other paraphernalia of a health campaign. This information will be at the disposal of any medical officer of health who cares to ask for it, and the results will be a great saving of time and effort to the staffs of public health departments. Further more, the council will recommend only what it has seen and approved. The official journal, *Public Health*, is published monthly under the auspices of the central council, and already its influence is felt throughout the country. The council has no intention of undertaking the production of propaganda material on its own account, and has no desire to enter into competition with existing societies, its aim is rather to assist these societies in their work and to suggest means whereby their activities may be made still more useful to the public. It is interesting to note that an agreement has been reached with the Central Medical Council as to the publication of health articles in the daily press. It is now accepted that such articles should be submitted to the Chief Medical Officer of the Ministry of Health for his approval, and that approval will be forthcoming provided they are (a) for the public benefit, and (b) free from the taint of personal professional advertisement. Articles of this nature may be signed by the author, and may then be distributed through one of the press associations.

Insufficient use has been made of broadcasting as a means of health education, and I would commend to you for your consideration the suggestion made by the editor of *Public Health* in the May issue of that journal. It is pointed out that the present method of broadcasting once a month a health talk lasting fifteen minutes is quite unlikely to make an appeal to those most in need of such education. One ends are likely to be better served by more frequent "four-minute broadcasts" on matters of special health interest at the particular moment. The suggestion appears to be full of promise.

May I say in conclusion that if our efforts are to be successful they must be continuous. It is no good having

ono health week a year if wo do little or nothing during the remaining fifty-one weeks. It is the constant driving home of the simple truths wo all know that will do most good in the long run. Above all we must avoid, as Sir Thomas Horder has so well pointed out, the creation in the public mind of any idea that health is an extremely difficult thing to secure or that there are any such things as the "secrets of good health." "Health is a broad and well paved road, Nature is both an excellent road maker and an excellent road monitor. Not only does it require very little skill, and but a modicum of good fortune to keep to it, the wayfaring man must be a fool indeed if he errs therein."

THE THERAPEUTIC VALUE OF THE HEAVY METALS IN PULMONARY TUBERCULOSIS *

BY

L S T BURRELL, MD, FRCP,

Physician to the Royal Free Hospital and to the Brompton Hospital for Consumption and Diseases of the Chest

THE heavy metals have a place amongst the many drugs that have been used in the treatment of pulmonary tuberculosis. Mercury and copper were both believed to cause fibrosis, and to lead to the healing of tubercle, but in practice it was found that they were of no value. A few years ago copper was much advocated, especially in Germany and Japan, in the treatment of tuberculosis, and very encouraging results were described at first. The intravenous injection of copper is frequently followed by a short febrile reaction, or even a rigor, which occasionally leads to improvement in the general condition of the patient. The same result is seen in shock produced by other means, such as serum, tuberculin, protein, colloidal gold, reaction to sun rays, etc. Chart 1 shows reactions following the subcutaneous injection of anti-tuberculosis serum in a febrile case of pulmonary tuberculosis.

CHART 1.

It will be seen that no reaction followed the injection of 10 c.c. of the serum, but the administration of 40 c.c. caused sharp reactions followed by a lowering of the temperature, later the patient had anaphylaxis and nearly died when 20 c.c. had been given, after this the temperature became settled, and she rapidly improved, being able to leave hospital and go to a sanatorium. A shock reaction may, of course, start an acute spread of the tuberculosis, which rapidly proves fatal, but improvement is so often seen to follow the initial shock that one is bound to doubt whether the treatment—be it gold or copper, serum or tuberculin—is acting by virtue of any specific action on tuberculosis. May it not be that the shock stimulates some defensive process in the body and thus leads to improvement? If this is the case it would seem immaterial which method is used to produce the shock, and up to a point I think this is so.

The metal which is most used at present in the treatment of pulmonary tuberculosis is gold, and the best preparation is a double thiosulphate of gold and sodium called "sanocrysin," which was made by Moellgaard. Chart 2 shows a febrile reaction after sanocrysin. The temperature later settled down to normal. In many cases, however, there is no apparent reaction, and yet the patient shows signs of improvement. While, therefore, some of the effects of sanocrysin (such as can be produced

by various other substances) are no doubt due to the shock, there appears to be some other factor besides this. The most notable change resulting from sanocrysin treatment is the diminution in the quantity of sputum and the disappearance of tubercle bacilli from the sputum, the chief indication, therefore, for using sanocrysin is when the sputum continues and contains tubercle bacilli. In the majority of cases I have chosen patients with chronic pulmonary tuberculosis where the disease is slowly progressing and tubercle bacilli are constantly present in the sputum. This type of case is very common in every sanatorium, and may be regarded as that which ultimately does badly, so that some additional method of treatment is much needed.

CHART 2.

Another type of case in which I have found sanocrysin of use is when collapse has been induced in one lung by artificial pneumothorax, and the disease begins to spread on the other side. In these cases it is sometimes possible to check this development and thus to secure the maintenance of the pneumothorax. In cases of acute pulmonary tuberculosis I have not found sanocrysin of great value, but if it is combined with pneumothorax I think the patient obtains the best chance. My practice is to induce collapse in the worst lung and to give sanocrysin in the hope of checking the spread of the disease in the other lung.

When sanocrysin was first introduced in 1923 there were many complications and cases of metal poisoning, but now it is usual to give smaller doses, and a serious complication is very rare. It is given by intravenous injection, and I start with a dose of 0.1 gram. If there is no reaction three days later I give 0.25 gram, and then at weekly intervals 0.5 gram, 0.75 gram, and 1 gram. I repeat this last dose three or four times at weekly intervals. If there is a reaction after one dose I wait until it has completely subsided, and then repeat the same dose if the reaction was a small one, or give a smaller dose in the case of a large reaction. In children, small women, or delicate, thin patients I do not give as large a dose as 1 gram, but stop when 0.5 or 0.75 is reached. It is very unusual to get a reaction under a dose of 0.75 gram, although in exceptional cases I have seen a reaction even after 0.1 gram. To avoid serious complications the injections should never be given at shorter intervals than one week (except after the initial small dose of 0.1 gram), and should not exceed 1 gram at a time. The complications that occurred in my series were:

1 Albuminuria was present in about half the cases, but was transient and mild. I did not have to stop the treatment on account of it in any case.

2 A metallic taste in the mouth was experienced occasionally, but only two in my first series of 60 patients had stomatitis.

3 Vomiting occurred directly after the injection in 20 per cent of the cases, but passed off quickly, causing no ill effect.

4 A few patients complained of rheumatic pains in the joints, and I had to stop treatment in one instance owing to the severity of these symptoms.

5 A slight febrile reaction directly after the injection occurred in one third of the patients but this settled down in a few hours. A temperature rising to 101° F or more—sometimes associated with a rigor—was not uncommon and occurred in 13 of my first 60 cases, but settled down within forty-eight hours in every instance. A long febrile reaction lasting a week or more was noted in only 4 cases in this series.

6 An erythematous rash occurred in 11 of my first 60 cases, and in 3 of these it was severe. In the severe cases the rash went on to a desquamative dermatitis, and was by far the most serious complication noted in any of the series. At the same time, all these cases with severe skin reaction did very well as regards their pulmonary condition.

7 Sometimes a little sanocrysin is spilt round the vein and causes a swollen and painful arm. A 10 per cent solution of sodium thiosulphate injected into the swelling will give great relief in these cases. For stomatitis or for

* Read in the Section of Tuberculosis at the Annual Meeting of the British Medical Association, Cardiff, 1928.

the dermatitis following the sanocrysin treatment a daily intravenous injection for three or four days of 5 cc. of this 10 per cent solution will often give relief

In the early days of the treatment serum was given before sanocrysin in order to ward off the complications. I have never found this of any value, and think its use has now been abandoned by most physicians.

RESULTS OF TREATMENT

It must be remembered that in all my cases the patients were having rest in bed, with pneumothorax or some other form of treatment. It is not possible, therefore, to give statistics which would be of any value in coming to a conclusion as to the direct results of sanocrysin. Moreover, the treatment has not been employed for a sufficient length of time to enable one to judge anything beyond its immediate results. It is possible, however, to form some idea of these by noting what changes take place when sanocrysin is given while the rest of the treatment remains unchanged. Chart 3 shows a chronic fibro-caseous case with pyrexia.

On March 7th daily injections of ethyl benzyl-cinnaminate were given for a fortnight, and after five days' interval a second course was given. It will be seen that the treatment had no apparent effect on the temperature, the condition of the patient and the quantity of sputum remained unchanged. On April 12th sanocrysin was started the chart shows that in a few days the temperature began to settle. The sputum became less, and after a reaction on May 15th, following 1 gram of sanocrysin, it dried up altogether. It is useless to draw conclusions from one case, but in this patient the improvement followed so dramatically when sanocrysin was given that it is at least suggestive.

In 28 cases where patients had chronic fibro-caseous tuberculosis and were slowly losing ground in spite of hospital or sanatorium treatment, I added sanocrysin to the treatment, and in 15 of these cases tubercle bacilli disappeared from the sputum in six weeks or less.

In this chronic type of pulmonary tuberculosis patients have periods of comparative good health alternating with others when the disease progresses, in other words, they have a series of relapses. Sanocrysin does not seem to prevent these relapses, but it does seem, in many cases, to check a relapse and bring about a period of arrest. Many of my patients relapsed, and in some the relapse was controlled by a second course of sanocrysin. I have not seen any benefit in chronic fibroid afebrile cases, but a course of sanocrysin may cut short an acute exacerbation arising in them.

Cases of very active bilateral disease sometimes do very well if treated by pneumothorax and sinocervism. I had 6 such cases in my first series, and 5 of them improved, 4 losing the tubercle bacilli. In acute condition sinocervism alone does not yield very striking results. Although sinocervism is not a specific against tuberculosis, and is most certainly not a cure, it may be regarded as a useful addition to other methods of treatment.

DIABETES MELLITUS AND HEREDITY.

B1

P J CAMMIDGE, M D

The possibility of heredity playing a part in the etiology of diabetes appears to have been originally suggested by Rondolet, a physician of Montpellier in the sixteenth century,¹ but nearly two hundred years elapsed before the idea was definitely formulated by Johann Peter Frank, who has also the distinction of having differentiated diabetes mellitus from diabetes insipidus. Most subsequent writers on diabetes mellitus accepted Frank's view, and many published statistics showing the proportion of their cases in which a family history of the disease had been traced. Frenchs, for example, stated that such a history had been met with in 98 per cent; Seegen gave a higher figure, 14 per cent; and Naunyn found a still higher proportion, 17 per cent—to quote only a few. Writing on this subject, Naunyn² declared that the more carefully the family history was inquired into the more often was evidence of heredity discovered and this would seem to be the experience of more recent authors, for, with the exception of John,³ who found only 97 per cent of his cases gave a family history of the disease, they have generally quoted figures in the neighbourhood of 25 per cent, while Hoegslag⁴ has reported as high a proportion as 43 per cent. Statistics and general experience alike, therefore, agree in indicating that diabetes mellitus, or a condition predisposing to its development, tends to run in families and is hereditary, but as modern work on genetics has demonstrated that purely statistical methods and general impressions cannot be relied upon when an attempt is being made to establish the inheritability of a character, other evidence must be obtained before a reliable conclusion can be reached.

One present exact knowledge of heredity in plants and animals has been gained almost exclusively by experimental selective breeding and analysis, but this method is obviously not applicable to man. The alternative usually adopted is to collect all the available data regarding the family histories of a number of individuals exhibiting the character under investigation, arrange them in the form of pedigrees, and compare the results with standard cases resulting from experimental work. In this way it has been found possible to demonstrate Mendelian inheritance in a number of deformities and diseases affecting man such as brachydactyly, tylosis, night-blindness, haemophilia, etc. Most of these conditions are rare and present striking features by which they can be readily recognized, so that the collection of the necessary information is not difficult once a family suffering from the abnormality has been encountered but with diabetes it is not so easy, for, in spite of the disease being comparatively common, it is unusual to meet with patients who are sufficiently acquainted with the intimate history of their family to make it possible to construct even a tolerably accurate pedigree of its incidence among their immediate relatives, and still less among distant connexions. On going through my records I find that 224 out of a consecutive series of 800 cases (28 per cent) gave an ancestral or family history of diabetes. In the majority the known facts are too incomplete for any reliable deductions to be drawn, but some patients have given pedigrees resembling so closely in essential particulars those obtained in experimental breeding that it seems worth while taking representative examples and considering how far they support the view that diabetes mellitus, or a condition predisposing to its development is transmitted as a Mendelian character.

Before doing so it will be helpful if I describe briefly the results of some of the breeding experiments with animals Mr Howard and I commenced several years ago with the object of throwing fresh light on the still obscure etiology of diabetes. Working with mice² we found that if those having a naturally high fasting blood sugar (116-120 mg per cent) were mated together they always produced offspring with similar high blood sugars, but that when mice with high blood sugars were crossed with others

having normal blood sugars (about 85 mg per cent) all the progeny possessed normal blood sugars. These findings indicate that a high blood sugar is recessive to a normal blood sugar in the Mendelian sense. Confirmatory evidence was obtained by mating the progeny of these crossings with each other. It was then found that if the mice with high blood sugars were mated with the seeming normal mice they did not produce all normal animals, as might have been expected from the previous experiment, but equal numbers of normal and high blood sugar animals (Fig 1, A), while when the animals with normal blood

FIG 1.—Experimental breeding of mice. H=High blood sugar N=Normal blood sugar (N)=Heterozygous normal (hybrid carrier)

sugars were crossed with each other the offspring proved to have high and normal blood sugars in the proportion of one to three (Fig 1, B). Both these results are in agreement with Mendelian expectation in the particular circumstances of the experiments, and demonstrated that the mice with normal blood sugars resulting from the mating of the original mice having high blood sugars with normal mice were what is known as heterozygous normals or hybrid carriers. Animals of this description, although apparently normal, transmit the abnormality to their offspring, with consequences which vary according to the way their mate, as the experimenters quoted show.

A third variation which from a practical point of view is of extreme importance, must also be considered. It was found that if one hybrid carrier was mated with normal animals from another stock, all the progeny had normal blood sugars. These again, when crossed with normal partners, only produced normal offspring, and so on for several generations, when, however, two related animals resulting from such crossings were mated with each other, or with mice from another stock having a similar ancestral blood sugar history, mice with high blood sugars appeared among their progeny in the proportion of one to three (Fig 1, C). By further selective breeding it was then proved that two out of the three apparent normals were in reality hybrid carriers, and that only one was actually normal and incapable of transmitting the abnormality to its descendants. It is consequently certain that in mice—and subsequent experiments have indicated in other animals also—a natural high fasting blood sugar is recessive to a normal blood sugar in the same way as albinism is recessive to colour. In addition to the fact that this is the first experimental proof of the transmission of a chemical abnormality in accordance with Mendel's theory, these results are of interest as demonstrating how such an abnormality can be dormant in apparently normal animals maybe for many generations, to appear again in their descendants under appropriate conditions of mating.

Since the abnormality of carbohydrate metabolism giving rise to a high fasting blood sugar in animals is undoubtedly a recessive character it is not unlikely that similar defects in the chemistry of the body in human beings may be transmitted in the same way, and that some forms at least of hyperglycaemia and glycosuria, or the conditions predisposing to their development, may consequently run in families like a high fasting blood sugar in mice. The relationships in a pedigree indicating that such is the case are briefly as follows:

1 If both parents are affected all the offspring will be similarly affected

2. If one parent is affected and the other is not, all the offspring will appear to be normal, but all will be hybrid carriers (heterozygous normals) and transmit the disability to their descendants

3 If one parent is affected and the other is a hybrid carrier, half the children, on the average, will be affected and half will be hybrid carriers

4 When two hybrid carriers mate, one quarter of the offspring, on the average will be affected and three quarters will be apparent normals, although two out of the three will be hybrid carriers and only the third will be actually normal

5 Since a hybrid carrier is merely a bearer of the affection and does not suffer from it, an affected individual need not have an affected parent, or even an affected grandparent or great grandparent, although evidence of the presence of the affection in the family can usually be found among collaterals

Owing to the single births, limited families, and monogamous habits of the human species, clear-cut evidence of heredity comparable in every respect with that furnished by the experimental breeding of animals cannot be expected, but careful investigation should reveal hereditary relationships in human pedigrees corresponding sufficiently closely in essential particulars to the experimental findings to make it evident that they are governed by the same principles if diabetes, or some forms of it, are transmitted as a recessive character

Clinical methods for estimating the sugar content of the blood are of such recent origin that it is rarely possible to trace back hyperglycaemia for more than a generation, so that reliance has to be placed upon the occurrence of glycosuria and the symptoms of diabetes in working out human pedigrees. On comparing such pedigrees with our mouse results it is evident that there is a close correspondence in many instances, although, as we shall see later, not in all

Take for example the case of a woman suffering from diabetes who stated that two of her brothers were similarly affected, but another brother and two sisters had been repeatedly examined for sugar with negative results (Fig 2). In this family the affected and unaffected were equal in number a condition arising in mice as we have seen, when an affected individual mated with a hybrid carrier (Fig 1 A). Further inquiry revealed that the woman's father was a diabetic and, although her mother was normal her mother's sister suffered from the disease consequently the mother was almost certainly a hybrid carrier

FIG 2*

That the disease, or a condition predisposing to it, behaved as a recessive character in this instance is also indicated from the fact that all the three children resulting from the marriage of the patient with a normal husband were found to be normal. Similar family histories are not very uncommon among diabetics, although it is unusual for the figures to correspond so exactly to Mendelian expectation

The experimental breeding of mice with high blood sugars showed that, when two hybrid carriers were mated, affected and unaffected offspring appeared, on the average, in the proportion of one to three (Fig 1, B)

This proportion was found in a family of which another patient (Fig 3) was a member, his sister and two brothers all being normal. The patient's father who was an only son was apparently normal as was also his paternal grandmother but his paternal grandfather was a diabetic consequently his father was probably a hybrid carrier. On the maternal side the mother herself the grandmother and the grandfather were all apparently normal yet as a sister of the mother had died of diabetes there seems little doubt that the mother as well as the father of the patient was a hybrid carrier

FIG 3

In both the preceding examples it was not necessary to go far back in the family history of the patient to discover

The explanation of the signs used in this figure applies also to the later figures

evidence of the transmission of the disease as a Mendelian recessive character. An interesting pedigree showing how in human beings, as well as in animals, the affection may be hidden for several generations in hybrid carriers (Fig 1, C) was given to me by a biologist interested in genetics who brought his only child, a daughter, suffering from diabetes (Fig 4). The father was free from sugar

FIG 4

himself, and no case of diabetes or glycosuria had been known among his direct ancestors for at least two generations previously, but, as his father's brother and his grandfather's brother had both died of diabetes, it seemed certain that he, his father, and his grandfather were all hybrid carriers. The mother of the patient was free from sugar, but she had a sister undergoing treatment for diabetes, consequently it may be inferred that the mother was likewise a hybrid carrier. Since there were no other children of the marriage, it is not certain that the Mendelian expectation of one affected to three apparent normals would have been fulfilled, but it is probable that it would, as both parents were apparently hybrid carriers.

The following is one of the most remarkable cases I have met with, from the point of view of heredity.

The patient was a girl of 6, who died of diabetic coma after an illness lasting altogether under three weeks (Fig 5). Two older sisters had died of the same disease, one when she was a year old and the other at the age of 18 months. The only surviving member of the family was a boy of 10, who had never shown any signs of diabetes and whose urine was found to be free from sugar although it was said he passed traces of reducing material in his urine at intervals when suffering from 'bilious attacks,' to which he was liable.

FIG 5

glycosuria could be discovered. The patient's mother, a woman aged 40 was known to have been passing sugar for about twenty years. One of her sisters had died of diabetes mellitus and two of diabetes insipidus, one at the age of 16 and the other at 20. A brother appeared to be normal, and had two normal children by a normal wife. The maternal grandmother of the patient, who was alive at the age of 70, had suffered from glycosuria for over twenty years but her husband was said to be normal. In the preceding generation there was no known history of glycosuria, and the great-great-grandmother of the patient was also said to have been normal, although her sister had died of diabetes. It would therefore seem that the disease was transmitted for at least two generations by hybrid carriers and then became manifest in the grandmother, probably owing to her mother having married a hybrid carrier like herself. Two of her daughters, including the mother of the patient developed the disease, most likely as a consequence of her union with a hybrid carrier and both showed it at an earlier age than their mother. In the next generation a rapidly fatal form of diabetes developed at a very early age in three out of four of the children most probably as the result of the mating of a diabetic with a hybrid carrier.

The weak point of this pedigree, as of so many others, is that the known history relates almost entirely to one side of the family and the other can only be inferred, but if the assumptions which have been made are admitted it would seem to be a fairly typical example of the transmission of diabetes mellitus as a recessive character. The earlier age of onset and increased severity of the disease with each succeeding generation is noteworthy, although the apparent tendency to hepatic disturbances on the father's side was possibly a contributory factor in the production of the final tragic results.

If the whole available pedigree of the case we have been considering is taken into account it suggests that the

diabetic tendency was transmitted as a Mendelian recessive character, but if only the last three generations are considered it might well be that it behaved as a dominant, for with a dominant character (1) all the affected individuals have an affected parent, (2) in families where both affected and unaffected occur their numbers are, on the average, equal, (3) none of the unaffected, although springing from affected parents, have affected descendants. Apparent dominance of this description is not uncommonly encountered in work on human heredity, and may be a source of error if the pedigree is short, there are, however, many cases in which the characters of a true Mendelian dominant are so plainly present that there can be no doubt some forms of glycosuria are transmitted in this way.

Take for example two boys, one aged 6 and the other 7 who were brought to me suffering from glycosuria (Fig 6). Their mother was normal but their father had been passing sugar from the age of 27, and his brother from the age of 30. The mother of these two brothers, who was still alive aged 70, was said to have developed glycosuria when she was about 50. Now this woman had been married twice, on both occasions to apparently healthy husbands, and from one of these unions the family referred to had originated by the other husband she had one son and two daughters all of whom had developed glycosuria about the age of 30.

FIG 6

Since it is unlikely that both husbands were hybrid carriers, and as, moreover, all the descendants of both marriages suffered from glycosuria, it is evident the disease must have been transmitted as a dominant character in this instance.

I will quote another example of the same type of transmission.

A girl, aged 14, was brought to me suffering from nocturnal enuresis and was found to be passing sugar in her urine (Fig 7). Glycosuria had been discovered in her mother and a maternal aunt at the ages of 45 and 40 respectively and her mother's brother was also said to be diabetic. The mother and the aunt had both married apparently normal husbands, but both had diabetic children—the patient in the one instance and a girl of 18 in the other. The maternal grandmother of these girls was alive and well at the age of 80 and when her urine was examined it was found to be free from sugar, her husband however, had died of diabetes at the age of 72.

FIG 7

Other examples could be cited, but space forbids, and sufficient has been said to show that defects of carbohydrate metabolism giving rise to glycosuria may be transmitted either as a recessive character, like hyperglycaemia in mice, or as a dominant character, like brachydaetilia or night-blindness in human beings. In my experience the former type occurs most commonly before the age of 40, while the latter is more frequently met with in elderly people, but as there is a tendency for both to develop earlier in successive generations, the age of the patient alone cannot be relied upon as an indication of the way the defect has been inherited. The dominant variety is almost invariably mild, and may persist for many years, even in young people, without causing serious symptoms or materially affecting the general health. The recessive form, on the other hand, is generally grave from the onset, is more difficult to control by diet, and is inclined to progress, corresponding, in fact, to the "true diabetes" of Naunyn and others. The recessive type tends to be self-exterminative, whereas the dominant variety, owing to its generally later appearance and comparative mildness, interferes little, if at all, with reproduction and length of life. Dominance is consequently the prevailing form of inheritance found when a series of cases of glycosuria of all descriptions is examined, and, as direct transmission from parent to child is more obvious than inheritance through hybrid carriers it bulks even more prominently in the results of researches on heredity carried out on purely statistical lines. This, no doubt, is the

explanation of the common belief that heredity is a favourable sign in diabetes, which, although true of the more common and obvious dominant variety, is not correct when the condition is inherited as a recessive character.

At present it is not clear whether the inherited factor is itself the determining cause of diabetes, or whether it merely predisposes to the development of the disease by subsequent illness or injury. The occurrence of severe cases without demonstrable cause in early youth and infancy is in favour of the former hypothesis, but the undoubted connexion of diabetes with infections and other recognized causes in some instances indicates that, in later life at least, an exciting agent is often necessary. It is possible that the diabetes of young people may arise from inherited defects of the recessive type, which prevent the development of the organism in a particular direction keeping pace with the increasing demands of the growing body, and as the inherited factor probably differs in intensity, so the period of life at which the symptoms of diabetes appear also varies. In this way we can account for the severe form met with in infants, the tendency for the disease to develop about the age of puberty, when, as was pointed out by Priscilla White,¹ it is frequently related to excessive height, and the influence of infections, toxæmias, injury, pregnancy, etc., when growth has ceased. The mild and relatively innocuous form transmitted as a dominant character is an entirely different condition, and, as it is comparatively rarely met with before an age when the vigour of the body is naturally beginning to decline, it would seem to depend upon the development of an inherited tendency to abnormally early failure of some function concerned in carbohydrate metabolism accelerated, as a rule, by acquired faults of assimilation and nutrition. The notoriously benign type of diabetes so common in certain races, particularly Hindus, Japanese, and Jews, is very likely of this variety, and probably depends upon an inherited dominant strain developed by a lifelong adherence to an improperly balanced diet.

Although there can be no doubt that heredity plays a part in the production of the defects of carbohydrate metabolism, giving rise to glycosuria and diabetes in many instances, there is not as yet sufficient evidence to justify the conclusion that an inherited factor is a necessary basis for their development in all cases. Should further research prove that such a basis exists, it would do much to simplify our ideas of the etiology of diabetic conditions by providing a common bond between the various forms, the differences in symptomatology, severity, and age incidence which occur being then accounted for by the character of the inherited factor and the nature of the exciting cause. Prognosis, too, would be more certain, for it would be largely determined by evidence pointing to the hereditary tendency being of the dominant or recessive type while the fact that the glycosuria associated with the former is mild and easily controlled, whereas the recessive form is generally progressive and more severe, would be of assistance in formulating an appropriate line of treatment. Even in the present state of our knowledge inquiry into the family history of a patient suffering from glycosuria will often supply information which is useful in treatment, and, by the reassuring prognosis it may suggest, go far to dispel the fear of "diabetes" the discovery of sugar in the urine arouses in so many people.

The main value of the evidence regarding the occurrence of an hereditary factor in defects of carbohydrate metabolism is, however, its bearing on the question of marriage. The marriage of diabetics is clearly inadvisable, and intermarriage between families where there is even a remote history of the disease is to be discouraged, but as our advice on such matters, although often asked, is rarely taken, the children and grandchildren, even to the third and fourth generation, should be watched and guarded as far as possible from exciting causes likely to develop a latent and inherited defect.

INJURIES OF THE EAR ARISING FROM FRACTURES OF THE SKULL*

BY

EDWARD D. D. DAVIS, F.R.C.S.,
Surgeon Nose, Throat and Ear Department Charing Cross
Hospital

In view of the increasing frequency of motor and street accidents, a discussion on fractures of the base of the skull from the aurist's point of view should be useful.

Patients suffering from this injury are usually sent for an aural examination some weeks after the accident, when deafness exists, or when the question of compensation arises. Inspection of the ears immediately after the accident would be more valuable and would enable the aurist to give a more accurate estimation of the damage. The additional information so obtained might be helpful in the treatment and prognosis.

The majority of the fractures of the base of the skull involve the middle fossa, and this proportion is to be expected when the base of the skull is viewed from below and it is seen that a line of weakness extends through both Glaserian fissures and the Eustachian tubes to the foramina laceria media, with the sphenoidal sinus as a connecting link. The two halves of the skull are more or less cemented together by the union of the basi-occipital and basi-sphenoid, and the fracture of the middle fossa usually follows this weak line wholly or in part. The thin roof of the canal of the tensor tympani and Eustachian tube, and that of the tympanum and mastoid antrum, lie in this line and are almost invariably involved in this fracture. The extent of the injury varies considerably with the violence and site of application of the blow received. Comminution of the thin bone of the tegmen sometimes happens, and spicules of bone are subsequently found in the auditory meatus. It is the middle ear which is practically always damaged in patients who survive and the capsule of the internal ear or labyrinth is rarely fractured. Only a few fatal cases of great violence show fractures of the internal ear, and J. S. Fraser,¹ in 1916, recorded, with microscopical sections four instances in which the fractures involved the labyrinth capsule in two and the middle ear only in the remaining two. The two middle-ear cases survived for a variable period and then died of meningitis, but the labyrinth cases were quickly fatal.

The external auditory meatus is often involved in the fracture when the line is through the Glaserian fissure and the fracture appears to split the meatus longitudinally, dividing it into an upper and a lower half, or, more commonly, a crack in the roof of the meatus is caused. In exceptional cases, where great force has occurred, the fracture has extended across the upper or anterior surface of the petrous bone into the internal auditory meatus. A smashing blow on the mastoid process has been known to fracture off the mastoid from the wedge of the petrous bone with injury to the lateral sinus. Fractures of the posterior fossa commence in the thin bone of the cerebellar fossa, and radiate into the lateral sinus groove of the same side. They then pass, either along the groove for the inferior petrosal sinus, or across the petrous pyramid near the inner edge of the lateral sinus, through the cancellous bone surrounding the mastoid antrum and semicircular canals, and behind and external to the internal auditory meatus. The various lines of fractures of the base of the skull can be seen in the museums of the Royal College of Surgeons and the medical schools, the tendency is for the fractures to take those lines indicated previously.

A moderate blow on the temporal fossa may produce a radiating fracture which cracks the roof of the middle ear, and blood effuses into the tympanum without rupture of the drum. No blood escapes into the auditory meatus but the typical bluish drum can be seen on examination. Four such cases have been observed, and the only indication was deafness. This lesion would not have been detected without an aural examination, and moreover

Read in the Section of Laryngology and Otology at the Annual Meeting of the British Medical Association, Cardiff 1928.

in such a case blood can occasionally be seen in the orifice of the Eustachian tube if the nasopharynx is examined with a mirror. These patients completely recovered their hearing in three weeks, when the blood in the middle ear had disappeared and the drum was normal. More commonly the upper half of the drum is ruptured and blood freely escapes into the auditory meatus and down the Eustachian tube to the nose and pharynx. If it is accompanied by the leaking of cerebro-spinal fluid, the fracture is a severe and dangerous one, opening up the subarachnoid space, and all such cases in my experience have been fatal. It is also significant that in the few recorded cases where the internal ear has been fractured the escape of cerebro-spinal fluid has been present. A detailed and thorough investigation of the injuries to the middle and internal ear arising from fractures of the skull has been made by J. S. Fraser, and he gave at the Otolological Section of the Royal Society of Medicine in 1916 a full description of the lesions found in a series of cases.

When haemorrhage from the ear is profuse and prolonged it is an indication that the middle meningeal artery or lateral sinus has been ruptured and urgent operative treatment is called for. The auditory meatus is sometimes a vent for this extracranial haemorrhage, and should never be firmly plugged. Fortunately the lateral sinus is not often ruptured, and the pressure of the brain and the increased intracranial tension are sufficient to arrest venous bleeding. Haemorrhage from both ears is always an unfavourable sign, and the mortality is 66 per cent, whereas in cases of haemorrhage from one ear the mortality is 39 per cent. The average mortality of all cases of fracture of the base of the skull is about 40 per cent.

In those cases where a middle-ear suppuration has existed before the injury, the probability of a meningial infection is very great and the prognosis is correspondingly unfavourable. In some cases the injury to the ear is followed by a local suppuration which materially adds to the damage, and spicules of bone from a comminuted fracture of the roof of the middle ear and meatus may be found. Mastoid suppuration has also been known to follow a fracture, and such a complication is liable to lead to a meningial infection.¹ Fraser reports a case of otitis media and meningitis which followed twelve months after the fracture of the skull. The injury undoubtedly facilitated the spread of the infection to the meninges. Some of these cases of local suppuration when seen late cannot be distinguished from the ordinary chronic middle-ear suppuration occurring without injury, hence the necessity for examining these patients as soon after the accident as convenient. The history of the absence of deafness and ear disease previous to the injury must be verified when the question of compensation arises.

A peripheral paralysis of the facial nerve has been recorded in about 46 per cent of fractures of the middle fossa of the skull. It arises in the more severe type of injury, and in a few cases the eighth nerve is involved as well, but in the small number of cases of facial paralysis seen by me the eighth nerve escaped injury. The facial nerve is involved by the fracture as it passes through the facial canal, particularly near the geniculate ganglion. The onset of the paralysis is almost immediate, but if it is delayed this is probably due to haemorrhage into the facial canal, when recovery of the paralysis is more rapid. All the patients seen with paralysis recovered even after long intervals.

The degree of deafness arising from fractures of the skull shows considerable variation. In a number of cases no deafness was reported, and twenty-five cases seen by me on account of deafness were all of the middle-ear type. The four patients in whom effusion of blood into the middle ear was the only detected lesion all showed marked middle-ear deafness when first seen, they completely recovered their hearing with the disappearance of the blood at the end of three weeks, and it was then impossible to detect any lesion. Another case seen twelve months after a severe fracture of the skull, in which the sixth, seventh, and part of the third cranial nerves were paralysed, revealed only a slight degree of middle ear deafness. The patients in whom fracture was followed by local suppura-

tion and inflammation suffered most loss of hearing, the deafness also became permanent. Any improvement in hearing usually occurs within about eight weeks from the date of the injury, and any deafness remaining after that period is permanent. I have not seen a case of genuine internal-ear deafness arising from concussion alone or from a head injury with such signs of fracture described previously. It is probable that the subjects of injury to the internal ear all die.

The treatment of these injuries to the ear is not always one of masterly inactivity, and a careful watch should be maintained for the onset of suppuration. Absolute rest in bed for a long period is essential, and the less that is done to the ear the better. The head is raised and a number of pillows are allowed. The auditory meatus is gently cleaned with spirit, a piece of sterile wool is lightly placed in the orifice and changed frequently. If there is any discharge of cerebro-spinal fluid the skin should be dried and smeared with an antiseptic ointment such as the dilute yellow oxide of mercury. Packing of the meatus with gauze, and, of course, syringing and drops, are to be firmly deprecated. If suppuration arises the whole aspect of the case is changed and vigorous methods should be adopted to establish free drainage. The drum should be incised if necessary, and there should be no hesitation in performing a simple mastoid operation at the slightest indication. The mastoid operation must be conducted gently, preferably by a motor burr or drill to avoid the jarring of the mallet and chisel.

The early recognition and treatment of suppuration is essential to the prevention of the dangerous meningial or intracranial infection.

UNCOMMON ILL EFFECTS OF SALVARSAN TREATMENT*

BY

W. J. O'DONOVAN, M.D.,

Physician to the Skin Department, London Hospital.

FATALITIES from salvarsan therapy do not stand in the front of the minds of the present generation of venereal specialists as they did amongst those who first used this drug with trepidation, and hope, in 1911. For when the arsenobenzols were originally introduced their use became associated with a formidable list of ill effects.

Experience has not demonstrated any certain method by which the type of patient unsuitable for salvarsan therapy can be picked out and treated in other ways,¹ neither old age, aneurysm, phthisis, chronic Bright's disease, high blood pressure, nor severe valvular disease of the heart can, in themselves, be considered as contraindications to its use. Ill effects may follow the administration of small doses², they may occur at the beginning, at the middle, or at the completion of a full course of salvarsan treatment. No hand of manufacture seems to be exempt, though at times a run of toxic effects from the use of any one make compels the physician for expediency to omit this temporarily from his armamentarium. It would be wrong to say that these remedies are safe remedies, though I would be the last to express anything but gratitude for their invention and the highest appreciation of the way in which this country has been saved from an epidemic of syphilis by the energetic establishment of venereal clinics after the war by the Ministry of Health. The rarity of congenital syphilis must be most gratifying to the officials of the Ministry of Health, when they reflect upon this matter.

Dr F. T. Burke has recently published a treatment of venereal disease (1927), in which four and a half pages are given on untoward effects of salvarsan therapy. The ill effects there referred to are

headache, shivering, vomiting, dyspnoea, palpitation, fainting, and so on. During the actual injection there may be nausea,

* A paper read in the Section of Dermatology at the Annual Meeting of the British Medical Association, Cardiff, 1928.

and vomiting a feeling of fullness in the throat a huskiness in the voice, the face may become flushed and the conjunctivae injected. At times there are severe cramps in the limbs and abdomen diarrhoea and cardiac distress and in many of such cases there is undoubtedly a psychological factor at work.

After these immediate reactions Dr Burke records an intermediate type of general or local urticaria or an oedema of the face and hands. Haemorrhagic encephalitis is included in this group, which may be rapidly fatal. He states that it seems to occur most frequently among alcoholics. I have seen but one case, and it occurred in an abstemious primipara.

Under the title "delayed reactions" he refers to "exfoliative dermatitis most prone to occur in neurotic patients." Jaundice is the other and last-mentioned untoward effect. This record might, I think, be fairly considered as a minimizing report when contrasted with the following two accounts. The list collated and published by the Salvarsan Committee of the Medical Research Council in 1922 recorded cases of urticaria, discrete erythema, papular erythema, exfoliative dermatitis, pemphigoid eruption, Raynaud's syndrome with gangrene, and purpura as toxic effects following the employment of arsenobenzol preparations. Mouradian⁴ published an appalling list of "accidents." These included cases of intestinal paralysis, serious uterine haemorrhage, cholera-fora diarrhoea, cephalalgia with migraine, epileptiform convulsions with sensorimotor troubles, febrile icterus, epistaxis, and haematuria followed by anuria.

The cases recorded below are outside this list and are of interest because of their gravity and apparent rarity. I feel certain that many cases are lost sight of through the dissociation of clinics from general hospitals or because such ill effects are delayed and the practitioner in attendance is not in touch with the salvarsan administrator.

CASE I—Post salvarsan Melanoderma

A dark well built man of 50 was infected with syphilis when 17, and was treated then with caustic to the sore and six months' mercurials. In 1923 his Wassermann reaction was positive and he received eleven doses of neosalvarsan between the end of December 1923 and the middle of January 1924 from a competent private doctor. After the eleventh injection his skin became so uncomfortable that he changed his doctor. He was sent into the London Hospital on July 1st 1924, with general erythroderma and free generalized exfoliation. A differential blood count showed stained blood leucocytes 14,300 per cmm, polynuclear neutrophils 80.5 per cent, polynuclear eosinophils 2 per cent, small lymphocytes 5 per cent, large lymphocytes 5 per cent, large hyaline cells 8.5 per cent.

By September 18th the exfoliation and redness had disappeared, the patient's skin was smooth but deeply pigmented as dark as an Indian's most uniform in the large flexures, but elsewhere on the trunk and limbs were numerous small circular areas of sharply defined white skin.⁵ A photograph of this startling condition was published in the *British Journal of Dermatology* 1925 (p. 87).

This condition has been vaguely recorded by two French writers, Goular⁶ and Bouteillier,⁷ Goular says that arsenobenzol erythroderma leaves some kind of melanoderma, and Bouteillier contrasts the great frequency of exfoliative erythroderma with the rarity of melanoderma and keratoderma. (See Case II.)

CASE II—Post salvarsan Maculo-melanoderma with Follicular Hyperkeratosis

An unmarried French polisher aged 26 came to the London Hospital in June 1927 with a primary syphilitic sore of six weeks duration together with inguinal adenitis and a faint macular eruption on the thorax. The Wassermann reaction was positive. He was treated with seven weekly injections of neosalvarsan one of 0.6 and six of 0.9 gram. Two weeks after the last injection both legs were red and swollen. He stayed at home until December 19th, giving a history that he had become red, had skinned all over and had lost a good deal of his hair. There was now a startling dappled appearance of the skin of his trunk, neck and upper limbs due to a macular non-infiltrated deposit of brownish black small ovals of pigment. There was no generalized adenitis, no relapse of the primary sore, but over the trunk thighs and arms both in front and behind was a most profuse development of projecting small uncoloured horny spines protruding from uninflamed pile-sebacous orifices. He was admitted to the London Hospital on January 2nd 1928 since then a very few spines have become reddened many have developed blackened tips and can be expressed like hardened comedones. In addition he has developed a moist eczematous plaque on his right wrist, and a small infiltrated pink slightly itching eruption of the right anterior axillary fold.

There are now no condylomata, no buccal lesions or pigmentation. The patient feels thoroughly well and has a negative Wassermann reaction. There is no arsenic in the urine and no albumin, the total and differential blood counts show no abnormality.

I showed this case at the Royal Society of Medicine on January 19th, 1928, and an excellent photograph will be found in the *London Hospital Gazette* of March, 1928.

CASE III—Multiple Subcutaneous Abscesses Associated with Arsenical Exfoliative Dermatitis

A woman, aged 32 attended my clinic at the London Hospital in February, 1927 with a primary sore and several secondary skin lesions. The Wassermann reaction was positive. She was given an intravenous injection of 0.6 gram of neosalvarsan on February 27th and this was repeated on March 6th 13th and 27th.

On April 4th the patient developed an irritating generalized morbilliform rash and was given sodium thiosulphate intravenously. She was admitted into hospital. The whole skin gradually became uniformly more thickened moist and weeping in the flexures cracked and scaling elsewhere. There was an abnormal enlargement of glands. There was profuse diarrhoea with occasional blood in the stools the temperature ranging between 99° and 102° F. The output of urine at times fell below 20 oz per diem and showed albumin. The patient lay supine in bed in a typhoid state.

During this time a great number of subcutaneous abscesses developed resembling the cold abscesses of tuberculous infections in that there was an absence of any surrounding inflammatory reaction. Over forty of these abscesses were opened one to two eggcupfuls of thick blood-stained pus being evacuated from each. Cultures from this pus showed the presence of *Staphylococcus aureus*. This phase extended over three weeks.

Towards the end of May the patient's condition began steadily to improve the thickening of the skin diminished the fissuring and exfoliation abated and no new abscesses were formed. There was no shedding of hair or nails. On June 12th she was able to walk unaided, there was only slight scaling of the limbs and round the orbits, and the patient's general condition was sufficiently good to allow of her discharge from the ward, she having rapidly and steadily gained weight. Her appetite remained good throughout the illness in spite of the fact that on more than one occasion recovery seemed a remote possibility.⁸

CASE IV—Cutaneous and Subcutaneous Necroses Perforation of the Nasal Septum with Arsenical Exfoliative Dermatitis

A man aged 42, a caretaker had a primary penile sore and generalized rash in 1903, and was treated when in the navy

FIG. 1.—Case IV. Salvarsan necrosis of skin and bone.

with thirteen mercurial injections. His Wassermann reaction was negative in 1920.

On August 16th 1927, he attended the syphilis clinic of the London Hospital with a well-defined ulcer on the right leg. The Wassermann reaction was weakly positive. He had four injections of neosalvarsan, 0.9 gram at weekly intervals. Six days after the last injection the eyes became puffy and he developed a universal lividity of the skin. He was admitted into the ward on October 3rd and treated at once with intravenous sodium thiosulphate. He showed a generalized erythema puffy face swollen limbs and temperature rising daily from 98° to 104° F in a fortnight. There was no enlargement of the spleen, no bradycardia. The urine showed a trace of albumin, no sugar deposit—few leucocytes epithelial cells and amorphous urates. No tubercle bacilli were found. Cultures showed the presence of *B. proteus*.

Blood examination on October 13th showed stained blood leucocytes 30,000 per cmm, polynuclear neutrophils 48 per cent, polynuclear eosinophils 41.5 per cent, small lymphocytes 7 per cent, large lymphocytes 1 per cent, large hyaline cells 2.5 per cent.

On November 7th the patient developed an acute abscess of the neck. A probe was introduced and passed between the skin and structure of the neck for three inches on the right side. In addition there were gangrenous sloughs on his back and right

FIG. 2.—Case IV. Salvarsan necrosis of bone of the

beels. The nasal septum perforated. The previous day the heels and back were in perfect order. A radiogram taken on December 22nd showed necrosis of the bone of the os calcis. At this time both legs were markedly pigmented. The patient was discharged well on January 3rd, 1928.

CASE V—Pulmonary Embolism

This man was first seen on January 21st 1927 with a primary syphilitic sore. He was treated at the London Hospital with seven weekly injections of novarsenobillon; the last six doses were 0.9 gram. Early in March he had some irritation of the neck which he treated with iodine, and on March 6th he was admitted with exfoliative dermatitis. He became extremely ill with high fever, delirium and albuminuria; he recovered from this, but his nasal septum perforated. On April 7th he complained of small boils on the left axillae and right groin. I examined him at 2 p.m. on April 12th when he seemed fairly well, able to sit up in bed unassisted, tongue moist, pulse 80 regular and exfoliation confined to the scalp, palms, and feet. At 10 o'clock that night he complained of distress in his chest; he became unconscious, cyanotic and died within five minutes. No *post mortem* examination was permitted, but the symptoms were sufficiently definite of pulmonary embolism from a clot dislodged from the iliac veins.

I have recorded uncommon but important ill effects following the administration of salvarsan remedies for syphilis. The knowledge of these possibilities makes it important that no practitioner should undertake the intravenous salvarsan therapy of syphilis without having facilities for immediate transference of his patients from an ambulatory clinic to a ward. The knowledge of these possibilities must be brought before the attention of the public if public support is to be sought for the compulsory treatment of venereal disease. Otherwise there will arise a feeling of resentment among the uninstructed should a severe accident or a fatality follow the compulsory administration of these most important but toxic remedies.

THYROTOXICOSIS AND INDICANURIA *

BY

LAMBERT ROGERS, F.R.C.S. Ed.,

ASSISTANT IN THE SURGICAL UNIT, WELSH NATIONAL SCHOOL OF MEDICINE, CARDIFF

This paper embodies the results of an investigation undertaken to discover what relationship existed between the intestinal dissociation of aromatic amino acids and thyroid hyperactivity. It is known that when tryptophane is decomposed in the intestine indole is eliminated in the urine as indican (potassium indoxyl sulphate), and as it is a simple matter to test for this substance it was thought that some light might be thrown on the question if the degree of indicanuria were estimated in a series of individuals suffering from thyrotoxicosis and compared with similar observations upon a series of non-thyrotoxic individuals.

It is possible, of course, that urinary indican may not be a true index of tryptophane decomposition, as the greater part of the indole may be eliminated in the faeces, but it seems reasonable to suppose that the urinary concentration of this substance will follow roughly the intestinal content. The degree of indicanuria, therefore, was measured in a large number of individuals. The technique adopted was a colorimetric one, the indican being estimated as indigoblue.

To 2 c.c.m. of urine an equal amount of hydrochloric acid was added, then 0.5 c.c.m. of hydrogen peroxide, the whole was shaken, and finally 1 c.c.m. of chloroform was added. The colour

was estimated after standing for four minutes. It was assumed that the acid converted the indican to indoxyl and sulphuric acid, and the peroxide promoted the oxidation of indoxyl to indigotin, the chief constituent of indigo blue.

The individuals whose urine was examined comprised three groups. Daily observations were made and graphs prepared, with the degree of indicanuria as the ordinate and the day of the week as the abscissa. The groups were comprised as follows:

Group I consisted of seven normal healthy persons.

Group II consisted of fifty-seven patients suffering from various conditions, but without evidence of thyrotoxicosis, the series including two cases of non-toxic goitre.

Group III consisted of patients with exophthalmic and other varieties of thyrotoxicosis. Twelve cases were investigated, one, a case of exophthalmic goitre, at some length, to see whether there was any effect on the urinary indican output during the slight attacks of post-operative thyroidism following ligation of the thyroid vessels.

The results were as follows:

Group I—Five of the seven persons investigated gave varying concentrations (Fig. 1 shows an indican curve from this group), while two

FIG. 1.—Healthy youth aged 18

males, aged respectively 23 and 16, gave completely negative readings for over a month.

Group II—

Thirty-eight women and nineteen men were investigated. 971 observations were made—580 on women, 391 on men. It is interesting to

note that of the observations on women 41 per cent were negative and only 5 per cent reached the highest degree of concentration, while of those on men only 23 per cent were negative and 18 per cent reached the maximum concentration (Figs. 2 and 3). In this group were two men and five women with urine completely free from indican.

FIG. 2.—Married woman aged 28 with a tuberculous abscess in the abdominal wall

FIG. 3.—Boy aged 17 with large endemic goitre.

Group III—Several of the most toxic cases in this group had high concentrations of indican. The curves generally resembled those of healthy subjects, and in the case investigated to see whether the post-operative reaction following ligations had any effect on the urinary indican it was found that there was no constant effect, a slight rise occurring after two ligations, no change after one, and a slight fall after another. Furthermore, careful observations during the clinical course of cases of exophthalmic goitre failed to reveal any constant change in the urinary indican that could be correlated with an increase or decrease in the degree of intoxication (Figs. 4 and 5).

FIG. 4.—Man, aged 30, with acute exophthalmic goitre.

FIG. 5.—Married woman aged 53, with severe exophthalmic goitre. The arrows mark points at which ligations were performed.

Since collecting the cases into groups, many more, particularly toxic and non-toxic goitre cases, have been investigated with similar results.

The findings may be summarized as follows:

(a) In healthy persons there may be little or no urinary indican without any evidence of thyrotoxicosis, and from

An investigation of the hypothesis which ascribes thyrotoxicity to an increased absorption of unchanged aromatic amino-acids from the intestine.

day to day the variations in the amount of indican are considerable

(b) In patients without thyrotoxicosis there may be no indican present in the urine, or on similar diet there may be much indican

(c) Goitre cases without thyrotoxicosis show no difference in the form of indican curve from that in toxic cases

(d) Toxic cases show concentrations which do not vary inversely as the degree of intoxication. Some well marked exophthalmic cases have much indican, some non-toxic cases little or no indican

The foregoing results do not lend support to the view that thyrotoxicosis is dependent upon increased tryptophane absorption from the intestine, as advanced in 1923 by Dr D J Harries.¹ It was at one time thought that thyroxine was derived from tryptophane, Professors Kendall and Osterberg regarding it as trihydro-ti-iodo-oxindole propionic acid.² Dr C R Harrington,³ however, has since shown that it is derived from tyrosine, from which he has synthesized it as a diphenyl ether

Further experiments were therefore undertaken to discover whether the absorption of unchanged tyrosine would result in thyrotoxicosis. Owing to the relative insolubility of tyrosine only small amounts could be injected intravenously, and, moreover, those experiments were limited to three volunteers. It is admitted that more experiments are desirable, but in the three performed there was no increase in the pulse rate following the injection, and no apparent effect on metabolism, as would be expected if thyroid activity depended upon the amount of unchanged aromatic amino acids reaching the thyroid

COMMENTARY AND CONCLUSIONS

It would appear, in the first place, that urinary indican varies in amount from day to day both in normal people and in those suffering from various diseases, sometimes being absent in health, at other times highly concentrated, tending more often to reach high concentrations in men, and to be absent from the urine of women; secondly, in exophthalmic and other varieties of toxic goitre there is no constancy in the concentration of urinary indican, which may be absent or present in varying degree, and thirdly, the variations are independent of the degree of thyroid activity

The urinary indican appears, therefore, to be of no value in determining whether a case of thyrotoxicosis is progressing or decreasing, and so enabling the surgeon to decide when to operate

Owing to the general similarity in structure of the molecules of thyroxine and adrenaline with that of tyrosine, and the fact that tyrosine is one of the essential amino-acids, it is reasonable to suppose that the hormones of the thyroid and suprarenal glands are ultimately derived from the tyrosine part of the ingested protein, but there is no evidence to show that the activity of these glands depends upon the amount of tyrosine available at any one moment from the alimentary tract, and without doubt the problem of the pathogenesis of thyrotoxicosis is more complex than merely a question of supply and demand, in which the supply is probably at all times very much greater than the demands made upon it

SUMMARY

1 Using a standard technique, colorimetric estimations of the concentration of urinary indican as indigotina were carried out for (a) healthy subjects, (b) non-thyrotoxic cases, and (c) cases of thyrotoxicosis

2 Graphs (indicauria curves) were made. There were no outstanding differences in the curves from each of these groups

3 The urine of women is more often free from indican than is that of men. Higher concentrations of indican occur more frequently in men

4 The concentration of urinary indican bears no constant relationship to the degree of thyrotoxicosis

5 The hypothesis which ascribes thyrotoxicosis to an increased absorption of unchanged aromatic amino-acids from the intestine is not confirmed

6 The statement that in all cases of well-established exophthalmic goitre there is no indican in the urine is not borne out. Several well-established cases gave high readings

7 Three volunteers were injected intravenously with small quantities of tyrosine. There was no effect on their pulse rates

8 The active principles of both thyroid and suprarenal are probably derived from tyrosine, but there is no evidence to show that the amount of these principles depends at any one moment on the quantity of tyrosine available from the alimentary tract

PAINLESS LABOURS

THEIR OCCURRENCE, THEIR INTERPRETATION, AND THEIR ADOPTION AS A STANDARD

BY

MARY DEGARIS, M D, B S MELB,
OCELOSO, VICTORIA

PAINLESS labours are exceptional in occurrence and are commonly regarded as being very rare, puzzling, and incomprehensible. A series was published in the *British Medical Journal* in 1906, and additional instances have been reported in previous issues of this year

Reference to case reports and to the literature makes clear that such labours are commonly associated with uneventful recoveries and vigorous infants, with laceration rare and slight, the labours are often primiparous, and successive labours are usually painless also. The desirability of comfortable pregnancies, easy labours, and uneventful recoveries is undeniable, and it is surely worth while trying to explain their occurrence

Before proceeding to a comparison of the painless with the usual form of labour it is necessary to mention certain features of average labour, all of which may be demonstrated in an analysis of a small series of cases. For instance, there is a great variation in the length of the first and second stages in different women, and also in the amount of suffering accompanying them; there is a definite rise in the forceps rate with the increasing duration of the first stage, and a short first stage tends to be followed by a short second stage, while a long first stage may be succeeded by a short, medium, or tedious second stage. The second stage is not uncommonly more endurable than the first stage, while its duration varies from two or three minutes to as many or more hours. The febrile puerperium is often related to an albuminuric or puerperal pneumonia, as is also the prematurity and stillbirth rates

The common symptoms of average labour are pain during the uterine contraction, sense of effort, sense of advance, sense of impending defaecation bearing down, vomiting, cramps, and not uncommonly fatigue; these common symptoms vary from patient to patient, not all are present in every one, while the intensity of the pain may be trivial, moderate, extreme or intolerable

The first three of the cases recorded here demonstrate that the painless labour resembles the average labour in every respect except in the absence of the pain during the uterine contraction. The signs are just the same—"show" flow of waters, dilatation of os vagina and perineum, the "crowning" the delivery of infant and placenta, and the varying duration of the individual stages of labour. The characteristic symptoms are also the same—sense of pressure, sense of something to be expelled, sense of advance, sense of impending defaecation, strange feelings and bearing down. In many painless or nearly painless labours the mother is the only one aware of the imminence of delivery, pain is so common that neither doctor nor nurse may pay sufficient heed to the mother's sensations, indicative as they are

Is the absence of pain sufficient to brand such a labour as abnormal? It may be unusual but it is not

pathological. Ought we not to argue from it that pain is not a necessity to successful childbirth, and to seek rather the cause of the pain than of its absence? In this way it might become possible to bring the pangs of labour under a real control through ability to deal with their causes, rather than merely by the palliation of anaesthetics. There is certainly nothing in the so-called definition of normal labour to contradict the suggestion that the natural painless labour is a normal labour. If it is a normal labour, should it not be adopted as the standard of normal labour?

Some deny the possibility of painless labour in a healthy woman, and attribute the absence of pain to hysteria, myelitis, tabes, or other disease of the nervous system, others admit the existence of painless labours in healthy women, but regard them as inexplicable. One author places both with one pain under the heading of pathological labour, another states that some pain is nearly always present, even though it may be slight. Nearly all authorities show a great reluctance to abandon the idea that pain is a necessity to healthy labour.

After reviewing all the available case reports and references of painless labour, and after actually witnessing one such delivery, and then comparing them with the ordinary case, I find that all labours may be arranged in a gradation, passing from the painless and nearly painless labour to the severe, the complicated, and the obstructed labour. The symptoms and signs are the same, though they vary in intensity from case to case—the same variation is true of all clinical conditions.

Painless labours fall into two main groups: (1) The pathological painless labour, where the woman is ill—for example, tabetic, myelitic, toxicæmic, etc. (2) The normal painless labour, occurring in the healthy woman: (a) the labour resembling defaecation—the type labour, (b) the sleeping labour (Dr Percy Allan describes these two in his article), (c) the painless labour requiring forceps delivery. An example of this is given in my case reports (Case 8), and several are in the literature. I have heard of others, but without details.

What interpretation may be placed on pain in labour, both as regards its presence and its absence?

All will agree that pain is a symptom, most will accept Mackenzie's statement that it is a viscerosensory reflex occurring during labour. No one will deny that it is dependent on the uterine contraction—it comes on with the contraction, increases with it, and dies away with it, indeed, No contraction, no pain! though not No pain, no contraction. It is a reflex indication of the uterine contraction, anything that interferes with the reflex arc, such as diseases of the nervous system, will interfere with the sensation of pain. Body poisons, as in toxicæmia, may have the same effect, thus we can explain pathological painless labours. In some women there is no viscerosensory reflex (pain), but there is a visceromotor reflex (vaginismus). Vaginismus also occurs not uncommonly in the average labour. In all varieties of labour this reflex may detain the head and hinder rotation, and necessitates forceps. This is the explanation of the painless labour requiring forceps, at least where impatience of the accoucheur can be excluded (see Case 8).

There are pains other than labour pains due to muscular contraction, but they occur only when the muscular action is abnormal or inefficient. In angina pectoris and the various colics the pain is a distinct indication of inefficiency, in them, also, visceromotor reflexes as well as viscerosensory reflexes may occur. The uterus is a hollow muscular organ designed first to retain and then to expel its contents, just as are the heart, the bowel, the bladder, and other hollow viscera. The physiology of all these must be very similar. The uterine contraction is not always painful. It is frequent during pregnancy and after labour, and probably also during menstruation. It is generally painless, but when painful gives rise to "false pains," after-pains, and dysmenorrhœas. The patient with false pains is very likely to have a tedious labour, especially a tedious first stage, and after-pains—that is, to have some inertia.

Since the uterine contraction is painless in some conditions, and in rare painless labours, is it not possible

that pain in labour is a borderline symptom of uterine inertia, and an indication of some defect in the contracting muscle—that labour is a crisis which discovers any fault in the uterine health? Dysmenorrhœas are commonly due to errors in the general health, so probably are dystocias. Since symptoms precede signs in most clinical conditions, the symptom of inefficiency (pain) may be present long before there is any sign (delay), as, indeed, we see every day. Child-bearing is so complicated a process that faults may occur singly or in combinations, and these errors may concern the mother, the infant, or the process of labour.

Painless labour, with spontaneous delivery in a healthy woman (see Cases 6 and 7), being the best and easiest labour known, should be taken as the standard or normal labour. Its adoption would give us an absolute, concrete and physiological standard of labour—namely, that a normal labour is one in which the uterine contractions act thoroughly efficiently, leading in a short time to the spontaneous delivery of a healthy infant, and causing little or no pain or suffering to the mother.

We imply by this definition that the normal uterine contraction is efficient and painless, and it becomes possible to study uterine action by the reflexes produced and the work done, this work is shown by the amount of dilatation of the os, and by the advance of the presenting part, the reflexes produced may be viscerosensory (pain), visceromotor (bearing down and vaginismus), and organic (vomiting and dyspnoea). The chief reason for the lack of progress in midwifery has been the absence of a definite standard of uterine efficiency, the painless efficient labour supplies this.

CASE REPORTS

My Case

CASE 1—A primipara aged 20 engaged me at the sixth month. She had quickened at four and a half months, there had been no sickness, and she felt very well. She had had measles twice but no other illness. The menses began at the age of 15, they were regular every four weeks, lasting four days and there was never any pain therewith. She has some false teeth, no crowns or pivots, and she has never had any fillings. She was remarkably well during pregnancy and took a mixed diet with a great deal of fruit, vegetables, and milk. Labour was a fortnight later than expected. Labour started at 11.10 p.m. with pains in the back occurring every twenty minutes, perhaps oftener, there was no distress. At 10.30 a.m. the patient was having 'pains' every ten minutes, the os was fully dilated and the membranes were intact. I ruptured the membranes which were visible, during a 'pain', the head being well down in the pelvic cavity. The patient complained only of a sense of pressure, not of pain, but she had had actual pain up to 10 a.m. felt first low in front, and then later in the back. This pain was evidently very slight. She vomited three times during the night. I stayed with her till the child was born, each pain did obvious work and was accompanied by a slight bearing down. The advance was slower than I anticipated from my first examination. At 1.32 p.m. a vigorous female child weighing 9 lb was born with very little caput. The mother complained of some pain with the last two contractions, due I think to perineal laceration, when questioned later she denied that she had felt any pain when the infant was born, but said it was an 'awful' feeling when the head crowned, immediately after which the perineal tear began. Some blood came out during the last three or four pains. Later she told me that there was actual pain in the first stage and also with some had had a weakness in the back, perhaps an ache. In the second stage there was only a feeling as if the bowel was about to act without real pain. She did not feel the tear and she did not like the feeling of distension of the vulva by the head when it was fixed, but it was not real pain. Her temperature rose to 99.6° F the first night. Her puerperium was otherwise quite uneventful, and she nursed her baby successfully. Involution was good.

Dr Winifred Kennon's Case (Melbourne)

CASE 2—A primipara aged 24, commenced her labour about 4 a.m. with some slight discomfort and sensation of abdominal uneasiness. Sixteen hours later there had been a 'show', but she was in no distress. The presentation was left occipito-anterior, the os was slightly dilated and the membranes were intact. At 11 p.m. she was bearing down slightly and the membranes were beginning to appear. She had no pain, and only felt she had something to push out. The membranes were ruptured artificially and at 12.30 a.m. the child was born. Dr Kennon reports: The patient could not understand when I told her to push when she got a pain because she did not have any pain, but if I told her when she got the bearing-down feeling to push she understood and delivered herself in that way. There was a small tear necessitating one suture. Involution was normal, but she could not feed her baby very well. Her diet during pregnancy was practically an ordinary mixed diet with the meat reduced in amount, she was particularly fond of fruit. Her upper teeth are artificial and she had no fillings.

Dr Yeatman's Case (South Australia)

CASE 3—A primipara aged 26 nine months pregnant alone in the house after breakfast felt some discomfort and thought the bowels were going to act but, recollecting her condition got into bed just in time for a healthy full term infant to be born. When seen, two hours later, the child attached to a perfect placenta was in the bed, the perineum was not torn. The patient did well until the third day when a rigor occurred and the temperature rose to 103° F. The uterus was explored and douches but nothing was found. The next day she was very ill and further examination revealed a badly decayed and foul-smelling molar tooth which was extracted at once. The puerperal sepsis gradually cleared up and she was convalescent in about a fortnight. In this case no vaginal examination could possibly have been made and no local treatment was given after extracting the tooth. She persisted in the statement that there was no pain at all, merely a sensation as if passing a large motion.

Dr Jovee's Cases (West Australia)

CASE 4—In this case Dr Jovee was sitting reading and the patient said in a perfectly natural voice that something was coming and birth followed immediately. She admitted a slight pain or two.

CASE 5—This patient a primipara while the head was crossing the perineum brushed a fly off her arm and said she felt no pain whatever only a sense of stretching and pressure. She weighed 7 st and had lived a natural life. The perverted starches were avoided and grains were ground daily by means of a small mill plenty of fruit and vegetables were used also tea made of blackberry leaves.

Dr Giommi's Cases (New South Wales)

Dr Giommi has seen seven cases in twenty-six years of Australian practice all were strong healthy hard working women. He considers the painless cases normal in every respect. He also has records of cases in Naples.

CASE 6—A woman aged 36 had given birth to four infants at Dr Giommi's private hospital the first two before either doctor or nurse could be informed for the birth of the other two a special watch was kept. The mother was healthy robust and hard working. She never had a pain although the womb could be felt contracting strongly. The waters broke with a gush and a few minutes later the child was born. Ten minutes afterwards the placenta was expelled without any trouble pain or inconvenience. Involution was more rapid than in the best of the average cases. She would only admit a certain discomfort at the passage of the head at the soft parts at the very last.

CASE 7—Aged 27 was lying in a tent. The womb was seen to be contracting well though there was no sign of pain and the foetal head appeared at the vulva painlessly. The placenta followed in ten minutes without pain and the womb became well contracted. She got up the next day and did her work as usual. Questioned as regards her feelings her answer was as in the previous case.

Dr Giommi's other cases were of a similar nature.

Dr Allison's Cases (New South Wales)

CASE 8—This patient was a frail anaemic woman of somewhat slow cerebration. The history of her first labour was that at 6 o'clock one morning she arrived at hospital saying that the waters had burst. The head was found to be well on the perineum. She had had no pain or discomfort but a feeling of stiffness low in the abdomen. There was no change at 3 p.m. so the patient was anaesthetized and forceps delivery was performed. The puerperium was uneventful. In her second confinement the onset was exactly the same including stiffness low in the abdomen the waters had burst and the head was on the perineum. She remained thus and comfortable for four hours with the head visible, and despite pituitary extract in two 1/2 ccm doses given hypodermically at an hour's interval she made no further progress. Forceps were therefore applied and the puerperium, as before, was uneventful. In her third confinement Dr Allison saw her at 10 a.m. She had taken castor oil one hour before and said she could just feel a little stiffness coming on. The head was well into the cavity of the pelvis the cervix being undilated and situated far back. At 2 p.m. she decided to walk a distance of one hundred yards to the loo pit. When half way there the child was born. She said later that she had had absolutely no pain nor even discomfort as she merely felt the touch of the baby on her thighs demonstrating its presence. This patient's pelvic measurements were normal and there was never any difficulty with the third stage of labour which lasted twenty minutes or thereabouts.

CASE 9—Dr Allison attended this patient at her second labour she said that Caesarean section had been pondered at her first confinement. External pelvimetry showed a flat pelvis and the sacral promontory could be easily felt by vaginal examination. This was at the fifth month of pregnancy. At the eighth month the foetal head was well into the pelvis the lower segment being stretched and the cervix bunched up posteriorly. The anterior shoulder appeared to be to the left near the iliac spine. The head was undoubtedly lying in a transverse diameter. The patient entered hospital four days before parturition and on the day of her confinement she complained of feeling heavy low in the abdomen. The membranes burst suddenly and unexpectedly and the nurse found the head appearing at the vulva after this the patient had two pains which were severe enough to cause her to cry out and a child was born weighing 7 lb. It was stated that this case under the commonest conditions would have required early induction or Caesarean section judging from

pelvimetry, but constant supervision showed the head past the brim with apparently nothing to prevent normal full time labour.

Dr Agnes Bennett's Cases (New Zealand)

CASE 10—A primipara who was a rather small framed woman suddenly woke with feeling 'water coming away she jumped up and threw herself on her knees just as the child emerged. This patient feared that this would happen a second time but it did not do so. The second labour was an average painful one but she preferred it to the former, from the shock of which it took her a long time to recover.

CASE 11—This patient awoke in the night to find the birth occurring. While her husband was telephoning for the doctor the child was born in the bed.

CASE 12—A delicate anaemic primipara was in hospital for mite natal treatment one evening she felt an urgent call to stool and the child was found in the pan alive and uninjured.

CASE 13—An unmarried girl was found in bed very pale weak and collapsed with a dead child the placenta and severe haemorrhage. She said that she had had no pain and did not know that the child was born.

CASE 14—A patient with threatened eclampsia was being treated with nicks and saline aperients when a child was suddenly born in complete membranes. Mother and child both did well.

References to painless labours and reports of such cases, have appeared in the literature from time to time. In the *British Medical Journal* in 1806 instances of painless birth were reported by Renshaw, Trevor Roper Irving, Young, Allan, Spurney, Scott Dickson, and Macphail in 1928 cases were recorded by Burn, Masser, Patton, Hobbs and Russell. In a discussion in the *American Journal of Surgery, Gynecology and Obstetrics* in 1911 cases of painless labour were reported, and again in the same journal in 1922. In the *Clinical Journal* for 1917 Percy Allan reports and classifies two cases, and refers to cases published in the *Medical Record* in 1892. References on scanty reports will be found in the following textbooks.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL

FOREIGN BODY IN THE BLADDER

THE case recorded on September 15th (p. 490) recalls a very similar occurrence which I met with many years ago.

A man nearly 80 years old who had led a catheter life owing to prostatic enlargement for eighteen years broke the end off his catheter in exactly the same way as described by Dr Ferguson and for the same reason—that is spasm at the neck of the bladder and urethra. I tried first to remove the broken piece which was about an inch and a half in length by passing a long fine sinns forceps down the urethra, but failed. I then told him that it would be necessary to administer chloroform and cut down on the impacted fragment but he refused to take an anaesthetic. It occurred to me that perhaps I could move it along from behind so placing him on his left side I introduced the left forefinger into the rectum and pushed firmly in the direction of the urethra the patient at the same time squeezing the penis in the same direction. To the great relief of both of us this manoeuvre was successful and the broken piece of catheter emerged from the meatus.

I suggest that anyone meeting with another case of this description might think it worth while to try this procedure before resorting to operative measures. The notes of this case were read and the specimen shown at a meeting of the Plymouth Medical Society.

Yelverton S. Devon.

H. W. WEBBER, M.D. Lond.

GUNSHOT WOUND OF THE CHEST

GUNSHOT wounds of the chest are perhaps of sufficient rarity in civil practice to make the following case worthy of record

A man, aged 46 was accidentally shot in the chest by a .320 revolver, twenty minutes later I found him lying on a bed turned partly on his right side unconscious, and very pale. There was a trickle of dried blood on his cheek below the right corner of his mouth but no other gross signs of bleeding. His respiration was slow and sighing his pulse was so rapid as to be almost uncountable with an occasional dropped beat.

The entry wound of the bullet was in the third left intercostal space close to the sternum and was sealed by clot the surrounding skin, in spite of the dried blood, could be seen to be contused. The bullet was felt under the skin in the eighth left intercostal space, four inches from the mid line. The blackening of the skin, over an area measuring roughly 3 in vertically by 1½ in horizontally showed that the bullet had been fired at close range.

Half an hour later he began to be restless and I gave him an injection of 1/6 grain of morphine. Before there was time for this to take effect the restlessness became very marked and he had to be held down in bed. This phase lasted about ten minutes, and is of considerable psychological interest since, although his remarks suggested a total lack of appreciation of his surroundings yet he told me later that he had wanted to sit up to get more air, and that it had caused him much mental distress to be held down. Two and a half hours afterwards he was still apparently unable to recognize me by sight, though on hearing my name he conversed rationally though feebly.

The bullet when removed under a local anaesthetic the same evening showed no marks except those made by the instruments in its removal. Both anterior and posterior wounds healed well and his progress in general was almost uneventful. During the first three days he coughed up ten or twelve goblets of blood, but was at no time distressed by cough. He was unable to lie on his left side as this caused some embarrassment of breathing and pain round the anterior wound. His temperature ranged from 100.2° F to normal, being more often nearer to normal while the pulse rate dropped from 110 to 90. At no time were there any abnormal sounds in his chest and the percussion note was uniformly clear except for a small area of slight dullness surrounding the posterior wound three days after the accident. On the fourth day he was removed to hospital in case a septic complication should ensue and necessitate operative intervention. It was fortunate that at the time of the accident he was dressing after a hot bath and the bullet only traversed a clean shirt and a new vest. He was able to return home after only ten days in hospital.

Except that he becomes easily tired and has a resting pulse of 84, he is now (three weeks later) leading a normal quiet life.

The patient states that at the time of the accident he felt a burning sensation, but hardly any pain, it was only when he looked down and saw blood that he realized that something serious had happened.

Grays Essex.

FATAL TRACHEAL OBSTRUCTION DUE TO
AN INFLAMED THYMUS GLAND

THE following case of death due to pressure on the trachea by inflamed thymus and lymphatic glands contains some details of general interest.

A boy aged 10 was seen on the fourth day of illness which began with cough and difficulty of breathing. The cough was croupy and the voice was hoarse. The tonsils and uvula were inflamed the temperature was 99.6° F, and the pulse 115. A dose of 8,000 units of antitoxin was given, and repeated the following day. The laryngeal symptoms rapidly disappeared and during the next three days he seemed so well that his mother wanted to give him solid food.

About 11.30 p.m. on the tenth day of his illness he was seized with a cough which continued during the night. On the following day his breathing was embarrassed especially when he moved. His voice was clear and respiratory stridor was heard this was louder over the left lung. There was marked dullness over the manubrium sterni but he did not complain of pain. It was evident that there was something pressing on the trachea and in a young patient thought was naturally directed to the thymus gland. I arranged for his admission into the borough sanatorium. Half an hour after admission he grew still worse. Dr Thorp performed tracheotomy which was of no avail, and the patient died three-quarters of an hour after admission.

A necropsy was performed, and on removing the sternum we found a swelling containing thymus gland and surrounding tissue. When incised a little blood-stained pus escaped and over the cut surfaces of the swelling were seen numerous small haemorrhages.

The pathological report stated that the lymphatic glands (pre-tracheal) showed marked acute inflammatory changes and suppuration the infecting organism being a streptococcus. The remains of a persistent thymus were present inflammatory changes were present in portions contiguous to the adherent inflammatory lymphatic gland but there was no suppuration in the thymus itself. The amount of thymus sent for examination was five or six times as large as the normal gland, and was not the whole of the gland.

The clinical summary of the case is that it was one of laryngeal obstruction which yielded to antitoxin, and that there was a later, and fatal, tracheal obstruction due to an inflamed thymus gland and to suppurating lymph glands.

Sunderland.

J C HAMILTON

A CASE OF TETANUS COMBINED WITH GAS
GANGRENE

THE following case of tetanus associated with gas gangrene, in which the patient recovered following intensive serum treatment, is of some interest.

The patient, a girl of 13 years, was admitted to the Reigate Guardians' Institution, under the charge of Dr C S Crichton, suffering from tetanus. There was well marked trismus, risus sardonicus, and head retraction. A week earlier she had met with a road accident, causing a dirty irregular wound of the left knee and also of the right elbow. Tetanus symptoms first developed on the fifth day. Her doctor saw her on the sixth day, and, after giving an injection of antitetanic serum, sent her to the infirmary.

Under anaesthesia the wounds were excised and dressed with gauze soaked in hydrogen peroxide. Serum treatment was begun with an initial dose of 6,000 units intrathecally and 6,000 units subcutaneously. Four days later the skin just proximal to the elbow showed a sharply defined dark area 4 in long by 1 in broad. This patch was covered with air vesicles of varying size up to that of a pea. As this appeared to be of the nature of gas gangrene, the area was freely incised the skin cut with a crackling sensation and the feeling was that of thin dry leather. The underlying tissues were healthy. B W and Co's recently introduced anti-gas gangrene serum for the treatment of intestinal obstruction was available and as an experiment 40 ccm were given intramuscularly and repeated on subsequent days.

The affected area did not spread but three days later there was a fresh development. A hand 1½ in broad and almost encircling the arm, appeared 6 in proximal to the old area, and a similar hand appeared round the wrist. The intervening skin appeared healthy. The condition now looked grave and the question of amputation arose. As the patient's general condition was not worse than when admitted and as the gas gangrene appeared to be purely superficial, the serum treatment was continued, and the fresh areas were again freely incised.

From that date no further extension took place and the parts quickly recovered. On the fifteenth day after admission all serum treatment was stopped. During that time she had received 102,000 units of antitetanic serum, divided between intrathecal, intravenous, and subcutaneous injections, and 1,300 ccm of anti-gas gangrene serum.

A portion of the skin was excised when the gas gangrene first appeared. The bacteriologist's report states that after heating to 80° C for five minutes and subcultivating anaerobically an abundant growth of a Gram positive sporing bacillus was obtained, which gave the morphological and biochemical reactions of *B. aerogenes capsulatus* (*B. welchii*). Prior to heating long chains of streptococci were also present.

It is interesting to note that the anti-gas gangrene serum used is prepared against *B. aerogenes capsulatus*. What influence, if any, the serum had on the favourable course of this case cannot be judged, but a hopeful line of treatment in a similar case seems to be suggested.

RUPTURE OF DIAPHRAGM IN A CASE OF
"VON JAKSCH'S ANAEMIA"

THE case here recorded seems of sufficient interest to merit publication.

A male child aged 1 year and 7 months was admitted subsequently diagnosed by Dr W E Cooke as a case of von Jaksch's anaemia. The infant showed no response to treatment on general medical lines.

On July 3rd, 1928 the temperature for no apparent reason, suddenly rose to over 104° F, and pyrexia was maintained during the ensuing days. On July 7th intractable vomiting commenced. The following day the temperature abruptly dropped to 97°, and the child died.

At the post mortem examination the findings confirmed the diagnosis. In addition the whole of the stomach was found in the thorax rupture of the diaphragm having occurred in the vicinity of the oesophageal opening. Apparently the gradually increasing tension in the abdomen had led to the rupture of a congenitally weak area at this spot. The child did not vomit in hospital until the day before death, but in support of a congenital hernia the relatives volunteered a history of flatulence, frequent vomiting of feeds and borborygmi.

I am indebted to Dr W E Cooke for permission to publish this case.

Reports of Societies.

EMPHYEMA

At a meeting of the Medical Society of London, on October 22nd, with the president, Dr J W Cunn in the chair, Dr C I Lakin opened a discussion on the diagnosis and treatment of empyema.

Dr C I Lakin said that while abscess of the lung was rare in pneumonia, empyema was the most common complication. There were two types of empyema that in which the collection of pus was simultaneous with the pneumonia and that in which the pus appeared as a sequel to these the terms synpneumonic and metapneumonic had been applied by Cameron. The latter was the more common, the synpneumonic type being mostly confined to children under 2 years old as part of a generalized pneumococcal infection, it was noticeable that in any case of empyema in a child tubular breathing was often heard through the fluid. Of the metapneumonic type there was a variety which might go undiagnosed, there being no definite history of pneumonia, though the child was obviously ill, with clubbing of the fingers, pallor, sweating, slight fever and dyspnoea. Empyema was probably never a primary infection of the pleura, and there was usually a pneumococcal focus present. The streptococcus produced the second commonest type of empyema, and this was the most serious form. It was important always to ascertain whether an empyema was diffuse or localized before there was any free opening of the chest. An x-ray examination would give useful information, and estimation of the intrapleural pressure would also help, since there was a wide range of oscillations in the absence of adhesions. The physical signs of empyema were, as a rule, those of a pleural effusion. Oedema of the chest wall and bulging of the intercostal spaces were more commonly described than seen, and with regard to displacement of the apex heart probably at least ten ounces of fluid were required before this took place. Interlobar and mediastinal empyema could be very puzzling, and in such cases Dr Lakin believed that radiological examination should precede the use of the exploring needle. Of all the signs of empyema there was not one which was peculiar to an effusion and which might not occur in other conditions, it was important to remember that mensuration of the chest would often show that the side containing fluid measured less than the sound side. In the diagnosis of interlobar empyema there was often a band of dullness over the second and third spaces in front. In differential diagnosis of this condition suppuration within the lung caused most difficulty but there was some help in the fact that the chest in abscess cases was "noisy," with many added sounds of a consonating character. Collection of pus below the diaphragm might give rise to difficulty, and in these cases it should be noted that pus would run out of a needle more rapidly during inspiration whereas in empyema pus emerged more readily during expiration. With regard to treatment Dr Lakin emphasized the need for revision of the old rule that pus should be evacuated as soon as found by costal resection. Aspiration had been substituted as a preliminary measure, and should always be performed when the diagnosis was made. Bacteriological and cytological examination of the fluid should next be made, and then the question when to operate decided. If the pus was offensive it should be evacuated at once. If it was non-offensive and active pneumonia was present aspiration should be continued until after the crisis when an operation could be performed more safely. The disadvantages of delaying the operation (such as thickening of the pleura) were slight. Local anaesthesia was preferable in all cases, and after the operation all steps should be taken to bring about approximation of the pleural surfaces. Sitting positions should be encouraged, and the use of Woulfe's bottles for blowing exercises.

Mr A Tudor Edwards defined empyema as a local collection of pus in the pleural cavity, and said that when the pus was diffuse the term "pyothorax" should be used. He insisted that the condition should never be regarded as an emergency requiring immediate operation. In

pneumococcal cases adhesions between the pleural layers formed early, but in streptococcal cases such adhesions occurred later, a sero-purulent fluid was obtained and an operation was contraindicated. When pneumonia was present aspiration should be employed at intervals until the active stage in the lungs was ended. Repeated aspiration might become increasingly difficult. It was the custom of the speaker to make an incision down to the pleura in such cases and pack this incision with gauze; this was removed when tapping was performed and was subsequently replaced. Local anaesthesia was required for rib resection, and complete closure was not justified. The correct treatment was to drain an empyema with approximation of the lung to the chest wall by adequate drainage, irrigation, maintenance of a negative pressure, and exercises. The dangers of irrigation arose from the use of a small tube and the production of positive pressure. For irrigation the chlorine group of lotions (eucal, etc.) was very valuable, since they appeared to dissolve the exudate on the pleura. The speaker used a special double tube with a flange, and irrigation was practised daily. In interlobar cases drainage should only be employed after the pleural layers had become adherent. The operation might have to consist of two stages, during the first of which the pleural layers were approximated to encourage adhesion. Under the age of 3 synpneumonic types were common, and aspiration should always be tried first. In chronic empyema it was first necessary to determine the size of the cavity to be dealt with. Then free drainage and irrigation were commenced, if the cavity did not appear to be getting smaller some further operation should be attempted. Decortication of the lung should be tried first, and if this failed the chest wall should be collapsed by some form of thoracoplasty.

Dr F J Poynton dealt with some of the problems of empyema in children. He described an apparatus for continuous aspiration devised by Mr T A Reynolds and himself in order to reduce the high mortality of empyema in infancy. He had used this method for more than twenty cases and he believed that there was room for improvement. In a series of seventeen cases treated since 1922 there had been six deaths: one from glioma of the brain, one from a safety-pin in a bronchus, two from meningitis, one from septicaemia later, and one had just faded away after apparent recovery. In three cases an operation for resection had been performed later. The difficulty in this method was to keep the cavity free from secondary infection. There was some difficulty in deciding when to remove the tube owing to the slow expansion of the lung in children, but taken all round, he believed this method of great value.

Dr Walter Broadbent described some cases of interlobar empyema. Dull areas were to be found over the second and third spaces in front, high up in the axilla and at the level of the spine of the scapula behind. The physical signs differed in every case, but the best situation for insertion of a needle was high up in the axilla. In cases of diaphragmatic empyema there was an area of dullness and silence in the lower axilla.

Sir Chambers Saxton inquired if Mr Tudor Edwards ever found it necessary to ligature the intercostal artery, especially in streptococcal or septic cases. He had always practised irrigation, and in the case of sudden death which he had reported in 1920 there was an abscess in the brain. For safety in irrigation he believed in the use of a big tube and antiseptic dressings should always be used to prevent secondary infection. The tube should not be removed too soon, and he recommended the use of oxygen where there was communication with a bronchus.

Dr C T Stebbing described his experiences with 150 cases of rib resection. This was indicated when the fluid became localized and frankly purulent. He believed that an operation should be performed as soon as this was the case. He thought x-rays of great use before operation to indicate the best site for drainage, he always made a large opening and put in a big tube, which should be kept in until the cavity closed. He agreed as to the value of antiseptic dressings but did not think suction drainage was necessary in most cases.

Reviews.

AMERICAN MEDICAL WAR HISTORY

THE War Department of the United States of America is to be congratulated on the possession of resources which enabled it to produce almost simultaneously, towards the end of 1927, three volumes¹ of its medical history in the great war. To the various sections published from time to time since 1921 under the direction of Major-General M. W. IRELAND, the Surgeon-General, have been added Volume II, by Colonel Joseph H. Ford, on administration in the American Expeditionary Forces, Volume VII, by Colonel William N. Bispham, on training, and Volume XIII, in Part I of which Major A. G. Crane deals with physical reconstruction and vocational education, while Part II contains an account of the Army Nurse Corps, by its superintendent, Julia C. Stimson. Those volumes are essentially works of reference, they are divided into sections, subdivided into chapters, complete with lists of tables, plates, charts, and figures. Consisting of 1,123, 1,211, and 998 pages, they weigh respectively 6 lb 7 oz, 7 lb, and 5 lb 15 oz. Included in each is an extensive appendix (covering 290, 456, and 645 pages of small print) containing important reports, copies of circulars, and information from different manuals.

The introduction to Volume II contains an interesting description of the general organization and development of the American Expeditionary Forces, the scope of the volume is indicated by the sections which, in order, deal with the organization and administration of the chief surgeon's office, medical activities of territorial sections, hospitals, evacuation of patients to the United States and discontinuance of hospitals, the army of occupation in Germany, and medical department activities with the American forces in France. For the purpose of this volume the period of war activities extends from April 6th, 1917, to December 31st, 1919. The outstanding feature in Section I is the outline of the medical department's struggle for an organization capable of handling the ramifications of the medical service, and for information which was absolutely essential if the army and the country were to benefit by having a medical personnel in Europe varying from 8.6 to 10 per cent of the total strength, and provision for the hospitalization of their cases on a 15 per cent basis. Three days after the Armistice instructions were issued to reduce the total hospital beds to 7½ per cent. The chapter devoted to hospital centres will repay study by those who may in the future be charged with the control of medical services on lines of communication or at bases. It may interest them in town planning, broaden their minds, and make them realize that peace time economies persisted in during active service can only lead to failure. Only one hospital centre is discussed at length. The chapter on base hospitals in France is an extensive piece of work, for the essential details are a précis compiled from individual records now filed in Washington. This may also be said of the chapter on camp hospitals. The hospitals are detailed by their numbers, each account including the date of organization, mobilization, moves, arrival in France, site, when ready to function, period of functioning, numbers treated, dates of leaving France, arrival in America, and demobilization. Names of commanding officers and of chiefs of the surgical and medical services are also given. Such details do not interest the general reader, a table would have lightened the volume and given the details at a glance. Section IV, on the evacuation of patients to America, contains certain facts worth noting and remembering. At the evacuation bases—St. Nazaire, Brest, and Bordeaux—there was a physical disability board, which examined all patients before deciding which cases were to be invalided to America. This is a most

important detail if the wholesale evacuation of patients likely to be fit for duty in a short time is to be prevented.

Volume VII, on training, is so crowded with facts that it will appeal only to officers who are either specially detailed for or interested in the exact type of work recorded. It is perhaps necessary to have a complete record, and it has been the aim of the volume to show how the medical department trained its personnel to fit the principles of medicine, surgery, and hygiene to military life. The first section deals with training in the United States, and the second section gives a detailed account of training in corps, army, and special schools in the American expeditionary forces in France.

Physical reconstruction and vocational education, the subjects forming Part I of Volume XIII, were early developed by the belligerent countries, but pioneers do not often speak of their work, and it is therefore all the more pleasing to read that "when we entered the war, nearly three years after its commencement, no pioneer road was left for us to follow with respect to the physical reconstruction and vocational re-education of our wounded or otherwise disabled soldiers and sailors. It was left for us merely to select a plan and to modify it to meet our own needs." How this was accomplished is shown in this volume, Part II of which is an interesting record of the organization and work of the Army Nurse Corps in America and in France.

The books under review, particularly Volume XIII, are well illustrated and printed on excellent paper in a type that makes pleasant reading but the method of putting copious reference numbers in the text, for verification elsewhere, tends to distract the reader's attention and is to be regretted. On the whole, we would have preferred less quotation of chapter and verse, trusting the historian to give a broad and fair survey.

DEGENERATION AND REGENERATION OF NERVES

To criticize the work of Ramón y Cajal is difficult, for the simple reason that one is so impressed by the extraordinary thoroughness of his work and by the painstaking wealth of detail. In *Degeneration and Regeneration of the Nervous System*² Cajal has given of his best. The book represents the fruit of eight years' research, and was originally published in Spanish in 1913, apparently most of the copies going to South America. It is a great pity that we have had to wait fifteen years for the appearance of an English translation of this remarkable work. It is a still greater pity that Cajal did not see his way to adding to the bulk of it by bringing it up to date thoroughly instead of merely inserting an "additional note" at the end of some of the chapters, giving an account, very cursory as a rule, of more recent work on degeneration and regeneration. Many readers will miss the name of Rio del Horta, which they had come to look on as almost a 'household word'.

The work is in two volumes, the first of which deals with traumatic degeneration and regeneration of the nerves. Cajal is a strong supporter of the neurotropic hypothesis of regeneration, but he discusses adequately the electrical theories of Kappers, Child, etc., and the mechanical theories of Heidenham and Harrison. A full discussion of these theories in view of the advances of the last few years from the work of Ariens-Kappers, Mauesco, and others would have added greatly to the value of the last chapter. The second volume is devoted to degeneration and regeneration of the nerve centres. This volume is divided into four parts, the first dealing with the sensory and sympathetic ganglia, the second with the spinal cord and the nerve roots, included in this part we have the optic nerve and the retina. The third part deals with the cerebellum and the fourth with the cerebral cortex. In these chapters the notion of injury, compression and cold, and of infections of various kinds, are dealt with. The section dealing with the cerebral cortex

Illustrated. 3 dollars.)

² *Degeneration and Regeneration of the Nervous System*. By S. Ramón y Cajal. M.D. F.R.S. In two volumes. Translated and edited by Raoul V. May. Ph.D. Harr. D.Sc. Paris. London. Milford Oxford University Press. 1928. (Med. 8vo pp. 769. 317 figures. 60s. net the two volumes.)

is perhaps the most interesting part of the whole work. Here the origin of the rod-cells or Stäbchenzellen of Nissl and the Gitter cells is well discussed.

The illustrations are very well done, and the two volumes reflect great credit on the Oxford University Press. The work has been so well translated by Dr RIGOLD MAX that it might well have been originally written in English. The feeling, however, after going through the two volumes, is one of disappointment that the whole work was not recast and brought thoroughly up to date when an English translation was being undertaken. Fifteen years behind the times is a long time in these days of co-ordinated and highly developed research.

FRACTURES—IN SPANISH

IN the preface to the first volume³ of his book on fractures Professor LAUREANO OLIVARES tells us that he has long hoped that the needs of Spanish and Hispano-American surgeons would be met by an authoritative work on fractures in his native language. He has now taken a long step towards supplying this want by the publication of this volume, in which the anatomy and physiology of bones, the pathology of fractures, and the various methods employed in the treatment of fractures are discussed. Another volume will follow in which fractures of the several bones and their various types will be described and their appropriate treatment indicated. As regards general methods Dr Olivares thinks that most weight must be laid on the use of bloodless proceedings so-called, which must, at present, and probably always will, be adopted in the majority of cases. Nevertheless a considerable amount of space is devoted to descriptions of methods of skeletal traction such as Steinmann's pins and different types of ice-tongs and bone-plates and bone-grafts. We are reminded that the author is treating of accidents in Spain or South America by finding at page 77 a most interesting radiograph of an incomplete but comminuted fracture of the tibia inflicted by a bull's horn. Such an injury in northern Europe is little likely to occur, except perhaps as a result of gunshot.

Adequate consideration is given to ischaemic paralysis as a result of fracture and its treatment, and there is a useful chapter on separation of epiphyses. The diagrams illustrating the effect of position in correcting or exaggerating the deformity of a fractured long bone, as in the case of fracture of the humerus or femur, are clear and instructive. A chapter on open or as we should say, compound fractures, includes gunshot fractures and gives much information on firearms and projectiles. We are glad to see that British and North American bullets do not interest the Spaniards, for we infer therefrom that the possibility of warfare between these three peoples is excluded from the author's mind. Thomas's splints on the contrary, receive due attention. The figures and plates in this volume to the number of 470 are excellent.

If the second volume is equal in merit to this Spanish surgery need no longer look abroad for an excellent guide to the treatment of all kinds of fractures.

PATHOGENIC MICRO ORGANISMS

FOUR fasciculi have appeared, forming parts of several volumes of the third edition of KOLLE and von WASSERMAN's admirable handbook of pathogenic micro-organisms.⁴ We mentioned the publication of previous fasciculi in our issues of May 7th, 1927 (p. 839), and February 11th, 1928 (p. 223). The new parts are as useful and comprehensive as their predecessors, particularly commendable is the full bibliography, and some of the fasciculi contain good illustrations. It is impossible to do more than mention the contents of each part for the benefit of readers especially interested in these subjects.

Part 21 of Volume I contains articles on the congenital transmission of infectious diseases, by Professor H. BRAUN

and Dr K. Hofmeier on the specificity of the exciting cause of infectious, and the basis of the teaching of acquired active and passive immunity, by Professor W. KOLLE and Dr R. PÜGGE, and on natural immunity, by Professor M. HAHN. In Part 15 of Volume II Professors E. P. PICK and F. SILBERSTEIN deal with the biochemistry of antigens and antibodies, Dr L. E. WALBUM with toxin and antitoxin, Professor E. PULBRAM with bacterial haemotoxins and anti-haemotoxins, Professor R. KRAUS with the toxins and antitoxins of vibrios, and Professor O. BAIL with bacterial agglutinins. Two new parts of Volume IV have been published of these, Part 17 contains articles by Professor W. v. LANGELSHIM on streptococcal infection, by Dr C. W. JUNGBLUT on scarlet fever, by Professor F. NEUFELD and Dr R. SCHULTZE on the pneumococci, and by Professor M. EISEL on tetanus. In Part 20 of this volume Dr J. ZEISSLER writes on the gas-producing infections in men, Dr H. FOTH upon anthrax, and Professor K. F. MEYER on botulism. Part 18 of Volume V contains articles by Professor E. WERNICKE and Dr H. SCHMIDT on immunity, serum therapy, and prophylactic vaccination in diphtheria, by Professor H. A. GINS on the *B. fusiformis*, by Professor B. MOLLERS on tubercle bacilli, by Professor H. SELTER and Dr W. BLUMENBERG on the pathology and mode of infection of tuberculosis, by Dr F. LOWENSTEIN on immunity in tuberculosis and tuberculin treatment, by Professor R. KRAUS on the basis of prophylactic vaccination with B.C.G., and Professor W. ZWICK and Dr J. WITTE on prophylactic vaccination against tuberculosis in domestic animals and cattle. In Part 16 of Volume VI Professor R. O. STEIN discusses ulcers molle, Dr S. L. FRANCIS tularemia, Dr R. ABEL the capsulated bacilli, Dr T. AXENFELD the infections of the conjunctiva, Professor E. KUNST the flora of the mouth, nose, and vagina, and Professor A. NISSE the normal intestinal bacteria and their relation to health. Part 22 of Volume VI deals with various topics, including coliform bacteria, described by Professor A. NISSE, swine erysipelas by Professor H. v. PREISZ, haemorrhagic septicaemia by Professor F. v. HUTYRA fowl cholera by Professor R. MANNINGE abscesses and suppuration in domestic animals by Professor F. GLAGE, infections associated with the breeding of animals by Professor H. MIESSNER and Dr R. WETZEL and an article on glands in cattle by Professor J. BONGERT. Part 19 of Volume IX contains two articles, the first, on foot-and-mouth disease, is contributed by Professor O. WÄLDMANN and Dr K. TRIANTHEIM while Professors P. UHLENHUTH, H. MIESSNER, and Dr W. GEIGOI have collaborated in an article on the virus of swine fever.

We commend highly the new additions to a series which has already deservedly won tributes of praise.

POSTURAL REFLEXES

UNDER the name of elementary posture reflexes Drs FOIX and THEVENARD in 1923 described certain phenomena observed in certain circumstances in the normal living muscles. Under the same title, *Les Reflexes de Posture Elémentaires*,⁵ Dr P. DELMAS-MARSALET of Bordeaux discusses at some length the practical application of a knowledge of these reflexes in diagnosis and treatment, especially as a means of discriminating lesions of the cerebrum from those of the pyramidal tract. The reflex which he has generally made use of for this purpose is that of the tibialis anticus, in the following manner. When in the relaxed and resting limb the foot is passively dorsiflexed and inverted, a contraction of the muscle occurs which does not at once disappear when the foot is released. This phenomenon would appear to be the opposite to the stretch-reflex of Sherrington. The author records the successive phases of this contraction and relaxation by means of a slightly modified Marey's myograph. The results of his many observations may be thus shortly indicated. In neuritis from lead poisoning, anterior poliomyelitis, tabes, hemiplegia (both flaccid and spastic), lateral and disseminated sclerosis, syringomyelia, and compression of the cord by tumour, the reflex is absent. In post-encephalitic

³ *Fractures*. Tomo I. By Laureano Olivares, Professor of Pathology and Clinical Surgery in the Central University and Surgeon to the Provincial Hospital of Madrid. Madrid: Javier Morata, 1928. (Sup. 8vo pp. xxii + 407, 470 figures.)

⁴ *Handbuch der pathogenen Mikroorganismen*. Begründet von W. KOLLE and A. v. WASSERMAN. Dritte erweiterte Auflage. Jena: G. Fischer, Berlin: Urban und Schwarzenberg, 1928.

⁵ *Les Reflexes de Posture Elémentaires*. Par P. Delmas-Marsalet. Préface du Professeur J. Pachon et H. Verger. Paris: Masson et Cie, 1927. (Med. 8vo pp. 174, illustrated 16 fr sans majoration.)

Parkinsonism, whether bradykinesia or not, or acute decerebration from epidemic encephalitis, and in paralysis agitans, the reflex is exaggerated. Certain therapeutic measures affect the duration and force of the phenomenon in diseased states. Thus, passive and active mobilizations diminish it temporarily. Certain drugs, such as hyoscine, have the same effect, and by their use it is possible to abolish this reflex, leaving the effects of pyramidal lesions evident. The therapeutic employment of this drug promises improved results. This study is very fully documented with case histories and many myographic tracings. Neurologists and pathologists alike should find it of considerable interest.

NOTES ON BOOKS

WE have received the first six issues* of a German series intended for the general practitioner, of which the subjects and authors are as follows: No 1, the initial stages of the most important mental diseases, by Professor Alexander Pilcz, No 2, disturbances of sleep and their treatment, by Professor Otto Maiburg, No 3, acute otitis media, by Professor Otto Mayer, No 4, diphtheria and other forms of sore throat, by Professor Carl Leiner and Dr F. Basch, No 5, convulsions in childhood, by Professor Julius Zappert, and No 6, glycosuria, renal diabetes, and diabetes mellitus, by Dr Herbert Elias. All the works emanate from well known authorities, and are written in a clear, concise, and practical manner. The work on diphtheria, which may be taken as an example, contains a brief epidemic logical introduction, which is followed by a fairly full clinical description of the varieties of the disease, the diagnosis and treatment, the various forms of sore throat in other infectious diseases, Vincent's angina, and all other forms of sore throat.

Dr W. A. FISHER of Chicago has produced a second edition of his book on *Ophthalmoscopy, Retinoscopy, and Refraction*. The publisher has done his work well, for the printing and binding are excellent, but we are not impressed by the subject matter. There are numerous fundus drawings in colour, but they are so small as to be of little value to the student. A fundus drawing $1\frac{1}{2}$ inches in diameter as the sole occupant of a page $8\frac{1}{2}$ by $5\frac{1}{2}$ inches fills out the volume, but such miniatures, though pretty to look at, are scarcely instructive. There is other waste of a more surprising kind. An illustration of an empty cotton reel would seem to be a work of supererogation, so also the devotion of a whole page to a couple of figures taken from a wholesaler's catalogue of spectacle frames. The text is short and scrappy, and is rather suggestive of a reproduction of lecture notes—sufficient as an outline of a discourse to be given, but somewhat cryptic to the uninitiated.

Dr W. G. AITCHISON ROBERTSON'S little book of *Aids to Public Health** (which we reviewed on its first appearance in our issue of July 7th, 1923, p. 22) has undergone rearrangement and enlargement, additions in particular having been made to the chapters on medical instruction of school children, maternity and child welfare and industrial hygiene. Although we find no mention of the Weil-Felix reaction in the section on typhus, the work in most respects has been brought well up to date, and the second edition will form a useful introduction to larger textbooks on public health.

The biological treatment of infections,⁹ by Dr A. JENTZER, contains a good summary of the pharmacological actions of the volatile oils, and those interested in this subject will find a useful bibliography containing some hundreds of references. The greater part of the volume is devoted to a description of the effects produced in septic conditions by the intravenous injection of a mixture of volatile oils and resins which has been named 'themsaline'. The author claims that this treatment produces remarkably beneficial effects.

Statistical Methods for Research Workers. By R. A. Fisher Sc.D. Second edition revised and enlarged. Biological Monographs and Annual. No 1. Edinburgh and London: Oliver and Boyd 1928. (Demy 8vo pp xi + 259 12 figures. 15s net.)

underlying theories, has been revised and extended in the light of the experience gained since the first edition appeared about three years ago. The principal change has been the addition of a chapter on the principles of statistical estimation, which received only general discussion in the earlier edition, and one of the tables has been extended to increase the range of its utility.

PREPARATIONS AND APPLIANCES

A SYRINGE FOR INJECTION OF VARICOSE VEINS. Dr A. A. MILLER (London, W.) writes: As is well known it is essential for a successful injection that the sclerosing solution should come in intimate contact with the inner coat of the varicose vein in order to injure the endothelium; this injury will be greater the more concentrated the injected solution. On the other hand it is necessary to make sure that the lumen of the vein has been entered, and this is done by aspirating some blood. The blood thus drawn into the syringe is apt to reduce the concentration of the sclerosing solution. It is therefore essential to

aspirate as little blood as possible and a syringe which allows the smallest quantity of blood to be clearly detected is indicated. I have used such a syringe for the last six months with most gratifying results. The essential part of it is the long fine nozzle made of polished glass magnifying the extremely fine lumen. An infinitely small amount of blood is readily observed, which could not cause any dilution of the sclerosing liquid; a fine short bevelled needle is used with the syringe. The syringe is manufactured by Messrs Charles Kung, 34 Devonshire Street, London.

PYELO-LITHOTOMY FORCEPS

Mr W. K. IRWIN F.R.C.S. (London W.) writes: When removing calculi through an incision in the renal pelvis I have often found difficulty in manipulating the ordinary type of forceps, especially if the patient is stout, the pedicle short and the kidney not readily mobilizable. I have therefore designed the instrument shown in the accompanying illustration. The inner end for

grasping the calculus is $1\frac{1}{2}$ in long, is bent at a right angle to the handle, and has concave fenestrated jaws. The handle portion is $2\frac{1}{2}$ in in length. With such an instrument one can work in a much more limited space than with a straight or nearly straight type. It has been made for me by Messrs Allen and Hanburys, Ltd., of Wigmore Street, W.

THE 'A AND H' KNIFE

WE have received from Messrs Allen and Hanburys Ltd. (48 Wigmore Street London W.) a specimen of their 'A and H' surgical knife with interchangeable blades and stainless steel handle. This detachable-bladed scalpel is made entirely in England. Its special features are the ease and safety with which blade and handle can be put together, the rigidity of the whole instrument when assembled, and the simple and convenient design of the grooved handle of hard stainless metal. The blades are made in three sizes from the best Sheffield steel. The several parts can be bought separately, but a complete set comprising handle and six of each size of blade, is sold in a metal box at 16s 6d. With this outfit the surgeon can depend on having a sharp knife ready for use at the shortest notice.

'TABLOID' EPHEDRINE HYDROCHLORIDE

Since medical practitioners have reported that in many cases the response obtained from the administration of half of a half grain of 'tabloid' ephedrine hydrochloride is adequate, Messrs Burroughs Wellcome and Co. now issue 'tabloid' ephedrine hydrochloride gr $\frac{1}{4}$ (0.016 gram) in bottles of 25 and 100. This, like all the firm's ephedrine products, is prepared from the natural alkaloid—the optically active isomer which rotates the plane of polarization of polarized light to the left. Dextro-rotatory ephedrine has little activity compared with its optical isomer. The racemic (optically inactive) synthetic ephedrine has been shown to possess only half the therapeutic activity of ephedrine carefully prepared from the genuine Chinese plant. Burroughs Wellcome and Co. add that they have ensured an adequate supply of authentic ma huang from China.

THE STATE OF THE PUBLIC HEALTH

SIR GEORGE NEWMAN'S REPORT FOR 1927

[FIRST NOTICE]

IN his annual report on the state of the public health¹ the Chief Medical Officer of the Ministry of Health advances four basic principles essential to the establishment of a sound national system of preventive medicine: there must be precise inquiry into, and accurate registration of, the essential data; there must be scientifically established and clearly formulated norms of health and physiological processes; there must be an ever-growing knowledge of the character and incidence of disease, its causes, and prevention; and, finally, as our practice of the principles of public health is ultimately moulded by practicality, public opinion, and financial resources, there must be national organization of health services. The problems of public health involve a consideration of the whole physical life of man, of everything which affects it, prolonging and enlarging it, or shortening and restricting it. How are healthy men and women to retain their health and grow in physical grace, knowledge, and capacity? How are children to be so nurtured as to grow up into healthy adults? How are the sick to be treated so that they may return healed as soon as possible to the ranks of the workers? These are problems that confront all who are concerned with the health of a community, Sir George Newman in his report presents the data on which any attempt to solve them must be based.

Population, Deaths, and Births

In 1927 the population of England and Wales increased by 200,000 over that of 1926. The bulk of this population—no fewer than 23½ millions—belongs to the age groups between 25 and 55; there are only six million children of school age, and only six million persons above 55 years of age. Males outnumber females in every age group up to 15, after that there is a steady preponderance of females, 654,172 children were born in 1927, much the lowest number for many years, 484,609 persons died. The decline in the birth rate and in the infant mortality rate is maintained, the death rate, on the other hand, is probably at its lowest point, and owing to the change in the age distribution of the population it may soon show a slight upward tendency. The principal causes of death in 1927, with the proportion per 1,000 of deaths from each cause were, diseases of the heart and circulation 201 (188 in 1926), bronchitis, pneumonia, and other non-tuberculous respiratory diseases 157 (150 in 1926), malignant diseases 111 (117 in 1926), diseases of the nervous system, 90 (103 in 1926), and all forms of tuberculosis 79 (82 in 1926). The death rate of infants under one month still remains high and shows no diminution in the last five years, but the death rate under one year has been brought down to only 70 per 1,000 births. As a low mortality rate is associated with a low morbidity rate this implies not only a great saving of infant life but a general improvement in the physical equipment of the present generation of children. The death rate among illegitimate children remains high being as many as 120 per 1,000 born. There is still no decline in the puerperal mortality rate, 2,690 women died in childbirth in 1927, and of these 1,026 died from puerperal fever—a preventable disease. There was an increase in the incidence and mortality of pneumonia, small pox, cerebro-spinal fever, and enteric, and a decline in poliomyelitis and encephalitis lethargica.

Epidemiology

Scarlet fever and diphtheria were more prevalent in 1927 than in 1926, but less fatal. The fatality rate was as usual, higher in diphtheria than in scarlet fever though the ratio in each case (52.5 per 1,000 in the former

and 6.8 per 1,000 in the latter) is the lowest recorded. Scarlet fever thus maintains the diminished severity which has characterized it in recent years. Five fairly considerable outbreaks resulted in a great increase in the incidence of enteric fever in 1927 over that of 1926—3,533 cases as against 2,739. The numbers of notified deaths from this fever were the same in the two years so that the fatality rate declined. The increased incidence and mortality from pneumonia in 1927 were associated with the recrudescence of influenza at the end of 1926 and the beginning of 1927, there were 67,757 cases with 37,242 deaths.

Small-pox

Small-pox increased in prevalence from 10,146 cases to 14,767, and the fatality rate, though small, was higher—3.2 per 1,000 in 1927, and 1.8 per 1,000 in 1926. In 1926 only one case occurred in Wales, in 1927 2,442 cases were reported. During the year 49 deaths occurred in respect of which small-pox was entered on the death certificate as the cause of death. Of these 35 were in unvaccinated subjects, 12 in subjects who had been vaccinated in infancy, and 2 in subjects in which the evidence as to vaccination was doubtful. An analysis of the age distribution of small-pox incidence in relation to the vaccinal condition of the patients is instructive. Only 26 vaccinated persons under 15 contracted the disease, no fewer than 6,013 unvaccinated persons of the same age group contracted it.

The Enteric Fevers

Exact information is lacking as to the relative incidence of diseases of the typhoid group, but the incidence of paratyphoid B fever appears to have increased in recent years. Paratyphoid fever is often so mild in character that many cases may escape detection and the number of notifications is therefore not a reliable index of its incidence. This fact may also account, in part, for the difficulty in tracing the source of infection in some outbreaks. The decline in typhoid mortality is attributed to the improvement of public water supplies, the prompt removal of faecal matter and house refuse, the early recognition and removal of cases to hospital, the education of the public in hygiene, and the improvement which has taken place in the technique of preparing, handling, and storing foods.

Diphtheria

The value of artificial immunization against diphtheria is emphasized in this section of the report. The improved methods and materials now used are effective and properly safeguarded, and though they may not afford immunity over the whole of life, they will, in most cases, do so during the early susceptible years. Three doses of toxin-antitoxin will produce full immunity in 80 to 90 per cent of children. Schick testing before inoculation is not necessary, but it is advisable to perform a Schick test three months after a course of treatment, and to give a fourth or even a fifth dose in cases that are then Schick-positive. The duration of immunity cannot be accurately estimated, but it has been shown to last nine years, by which time it becomes merged into the immunity naturally acquired with increasing age. The view is expressed that no local authority has done its duty until every parent in its area knows that his children can be thus inoculated with reasonable certainty of complete immunity. Not only are most young children susceptible, but they are more likely than older ones to take the disease in a severe form. Most deaths occur under five. It is useless to wait until an epidemic and then inoculate; protection is not complete for several months and immunization should therefore occur when there is no immediate fear of exposure to infection.

Scarlet Fever

Scarlet fever antitoxin is being increasingly used, and has proved effective in treatment. Administered early it lessens toxæmia and diminishes the risk of septic complications. On the other hand, it has no direct curative effect on already existing complications. The material for performing the Dick test and for producing active immunity with diluted toxin are not yet sufficiently standardized to justify their general use.

¹ On the State of the Public Health. Annual Report of the Chief Medical Officer of the Ministry of Health for the year 1927. London: H.M. Stationery Office. (3led. 8vo. 2s. 6d. net.)

Encephalitis Lethargica

There has been a progressive decline in the reported incidence of this disease since the peak year of 1924. The figure for 1927 was 143. The ratio of deaths to reported attacks continues high, and if one adds the deaths following the chronic effects of this disease, even in patients who may originally have been classed as "recovered," it appears that encephalitis lethargica eventually contributes to the death of 35 to 40 per cent of known cases. The sequelae of encephalitis lethargica continue to present serious problems in the administrative care of its victims, 45 to 50 per cent of all cases show various degrees of permanent disability. About half of these develop Parkinsonism, which, sooner or later, in the great majority, proves fatal. Mental impairment is almost invariable, especially in young children, and in 25 per cent of patients who do not recover completely from the acute attacks this impairment is a serious problem. Probably 50 to 60 per cent of patients suffering from the sequelae of encephalitis lethargica require special after-care and treatment—either close observation and control on account of their mental or moral disability, or nursing and after-care on account of their physical infirmities. The first group includes some who appear likely to profit from remedial and re-educative measures. The "encephalitis unit" at Winchmore Hill is an attempt to deal with the administrative problem of post-encephalitis lethargica. It not only provides treatment and after-care, but functions as an observation centre and clearing house, where cases are grouped according to their after-care necessities, and, so far as possible, are allocated accordingly. The adolescent case, subject to serious conduct changes and requiring observation and control, has not yet been adequately dealt with. It is suggested that large cities might combine on a regional basis to provide institutional resources for encephalitis units dealing with all post-encephalitic patients, including those who might be unsuitable or ineligible for other institutions.

Tuberculosis

The number of deaths from all forms of tuberculosis was 38,173, as compared with 37,525 in 1926. These figures, though they show an increase over those of 1926 (in which year there was an unexplained sudden drop), are lower than those of 1925, and in general the downward trend in this death rate is maintained. Notification returns are still unsatisfactory, and in some areas the number of notifications is only about 70 per cent of the new cases that come to the knowledge of the local authorities. Moreover, in some areas very little attempt is made to persuade contacts of newly notified cases to attend for examination. Where attention has been given to this point a considerable number of contacts have been found suffering from tuberculosis at the stage of their malady which gives the best chance of a successful issue to treatment. There is occasionally an unfortunate tendency to keep patients attending the tuberculosis dispensaries without coming to a clear decision on the diagnosis. Throughout the country, however, the diagnosis of 92.9 per cent of dispensary cases is completed within three months. The importance of repeated sputum examinations for diagnosis, prognosis, and selection of cases for institutional treatment is strongly emphasized. Many patients are classed as F.B. negative, not because the bacillus is shown to be absent, but because sputum examination has been neglected, a fact which robs statistical studies of much of their value. England is far behind America and a number of other countries in the use of x-rays for confirmatory diagnosis. Local authorities which have failed to consider sympathetically the requirements of tuberculosis officers in this matter are largely responsible. It must be made clear that expenditure that helps to achieve accurate and early diagnosis of tuberculosis is not only justifiable, but is probably a real measure of economy. Cases undergoing sanatorium treatment may be classified as early, intermediate, and advanced. Many of the intermediate type are kept in sanatoriums for six months or longer, though it is suggested, they would probably do better with shorter periods of treatment, repeated when relapses occur or are imminent. The need for prolonged treatment in early cases offering real hope of arrest, and in advanced dangerously infective cases, is stressed.

Methods of Treatment of Tuberculosis

Under this heading a review is made of the immediate and end-results of treating tuberculosis by artificial pneumothorax and other surgical procedures, by sanocrysin, and by tuberculin, and an account is given of B.C.G. immunization. The information given in the annual report for 1925 as to the late results of treatment by artificial pneumothorax is supplemented by a report of an investigation into the after-histories of 111 patients so treated during the past ten years. The results have continued to be extremely encouraging. Sanocrysin is still under investigation, with a slight balance of evidence in favour of its use in carefully selected cases. Dr. Burrell considers that the acute bilateral case in which the worse lung can be treated by artificial pneumothorax, and the type of case in which the tubercle bacillus persists in the sputum in spite of prolonged treatment and improvement in other respects, are particularly suited to sanocrysin treatment. Tuberculin is still out of favour, but more information about Professor Calmette's B.C.G. is required before a definite view as to its value can be arrived at. According to Calmette a comparison of the mortality of vaccinated and unvaccinated children in contact with tuberculous mothers shows that the rate for the former was 6.6 per cent, and for the latter 24 per cent. A close analysis of these figures by A. Woolgren shows the need for more detailed information, especially as to the mortality rates of vaccinated children brought up in contact with tuberculous mothers, before Calmette's claims can be fully accepted.

Mortality in Pulmonary Tuberculosis

A study of mortality curves suggests that there are at least two independent influences affecting the mortality from pulmonary tuberculosis in adult life. The first, to which females appear to be more sensitive, produces its maximum effect in early adult life—in the 20 to 25 age period. The second exerts its maximum effect between the ages of 40 and 50 in the case of males, and somewhat earlier among females. It is suggested that pulmonary tuberculosis exerts its maximum biological effect in early adult life, and that urbanization is responsible for the high mortality in middle life.

THE GENERAL PRACTITIONER AND PREVENTIVE MEDICINE

PRESIDENTIAL ADDRESS TO THE SOCIETY OF MEDICAL OFFICERS OF HEALTH

THE annual general meeting of the Society of Medical Officers of Health was held on October 19th, when Dr. JOHN HOWARD-JONES, medical officer of health for the county borough and port of Newport, Monmouthshire, was installed as president of the society, and delivered an address on "The role of the general practitioner and specialist in preventive medicine."

Dr. Howard-Jones began by recalling the extent to which knowledge of disease had been effective in reducing the death rate and infantile mortality in recent years, while public health efforts had been practically confined to the removal of the more obvious causes of sickness and death, a stage had now been reached when, beyond routine work, attention could only be devoted to the individual and the application of the laws of physiology to the prevention of disease. Each individual must realize his responsibility for the preservation of his own health and that of those under his care. In the public health service there was a relatively small percentage of those engaged in the practice of clinical medicine, he thought they must agree with Sir Arthur Newsholme that complete success would not be achieved "until means are discovered for training and enlisting every medical practitioner as a medical officer of health in the circle of his private or public practice, and of securing his services not only in the early and prompt detection of disease, but also in the systematic supervision during health of the families under his care, and in advising them as to habits or methods of life which are inimical to health." Dr. Howard-Jones called attention to the statement in the evidence given by the British

Medical Association before the recent Royal Commission on National Health Insurance "The alleviation or cure of morbid conditions when once they have arisen is, relatively to other matters, a minor part in the campaign for public health." He proceeded to show how the participation of the general practitioner in preventive medicine was being advocated from all quarters and in most countries, and to discuss those particular problems which fell outside the routine work of the medical officer of health.

Maternal Mortality

It was a deplorable fact that maternal mortality in this country had been practically stationary for nearly twenty years, in spite of the gradual substitution of the old untrained midwives by partially trained women, and the provision of medical help in cases of emergency before, during, and after childbirth. Unfortunately, however, more attention was paid to the treatment of symptoms than to the prevention of disease, and this in many towns led to unnecessary instrumental intervention, which was now recognized to be prejudicial to mother and infant. The time had come to reconsider the whole subject. As regards the national insurance maternity benefits no conditions were laid down as to how the recipients should spend the money, it was generally felt, therefore, that the administration of these should be co-ordinated with the maternity and child welfare service. The more recent records of some of the most enlightened midwifery departments of the great hospitals afforded gratifying evidence of the value of adopting preventive principles in the practice of midwifery. Dr Howard-Jones next reviewed the proposals of the British Medical Association and others. It was urged that provision should be made for the attendance of a doctor and a midwife at every confinement, and that while the midwife should usually conduct the normal delivery, the doctor would be responsible for ante-natal examination and supervision. He would attend at the confinement if difficulty arose, and also during the puerperal period as the case required. There should be consultant and specialist services for difficult cases and local authorities should provide accommodation in institutions under the maternity and child welfare scheme. Such a plan would ensure a definite place in the maternity scheme for the medical practitioner, it was most desirable that he should play a definite part in a well-organized maternity scheme, since after supervising the ante-natal care of a patient he ought to continue in charge until she was restored to normal condition, if possible.

Teaching of Midwifery

The organization of a systematic study of the woman during pregnancy was a recent development at the medical training schools, as an element in the training of the medical student and the pupil midwife, ante-natal work had hitherto been entirely fortuitous instead of being systematized and compulsory. Individual general practitioners throughout the country had, however, acquired for themselves the necessary knowledge and had devised admirable schemes for the women under their charge.

Discussing the causes of foetal and neo-natal mortality, Dr Howard-Jones quoted various authorities to illustrate the need for and the value of, ante-natal care and preventive work. The public needed education in regard to the advantages of preventive midwifery over the present popular but largely unnecessary delivery by instruments—with its greater danger of sepsis and trauma to mother and infant. It had been repeatedly stated in official reports that the teaching of obstetrics and gynaecology in most of, if not all, the medical schools in Great Britain left much to be desired. The new curriculum in midwifery included a certain amount of training in midwifery, in view of the fact that the deaths from premature birth and diseases of early infancy exceeded 25,000 per annum, this provision could not be regarded as premature. Midwifery was primarily physiological, and if conducted on preventive principles the pathological aspect of the work would be reduced to a minimum. Some midwifery teachers were doing great service by emphasizing the importance of ante-natal supervision and of dealing with

labour on physiological lines. Referring to the tendency to curtail the number of children in each family, the speaker said that from the parents' point of view the necessity for skilled ante-natal and natal care was assuming serious importance. There would be an increased proportion of first births, and these required greater supervision. Midwifery in industrial practice was generally underpaid if they were to secure ante-natal and post-natal treatment the question of remuneration would have to be reconsidered. The public would have to be educated up to paying for preventive midwifery, and the State and the local authorities would have to revise their present policies.

Co-ordination of Health Services

The Poor Law service included some 4,000 part-time or whole-time medical practitioners, this medical service was never based on preventive principles. Up to the present time it had not been co-ordinated with preventive medicine—to the great disadvantage of the public health. Opportunities would soon be available for remedying this state of affairs, but success would depend upon the spirit in which the central and local authorities undertook the necessary reforms. The aggregation of Poor Law medical relief, maternity and child welfare schemes, school medical services, mental hospitals, mental deficiency services, pensions medical work, public health services, and national health insurance amounted to a partial State medical service. Some of these branches were based on the ideals of preventive medicine, but the more costly were not. According to its preamble, the National Insurance Act was to "provide for insurance against loss of health and for the prevention and cure of disease." Prevention was given priority over cure, but it could not be denied that the Act continued the old-established idea of medical treatment by a visit and a bottle of medicine for a third of the population. The great fault in the present system was that medical advice was only obtained after disease had actually attacked the patient. Fees would have to be increased and the size of "panels" reduced to enable the general practitioner to practise preventive medicine among his patients. Referring to the need for the teaching of medicine on physiological and hygienic lines, Dr Howard-Jones said that those teachers who were impregnated with the old "pathological" principles would probably not help much in this direction consequently it would take many years before much real progress would be made. He understood that post graduate courses which would enable practitioners to prepare themselves for more active participation in this preventive medical work were not available in this country. Unless something were done in this connexion the general public would not participate in the benefits to be derived from the great advances which had been made in physiology, biochemistry, and dietetics by those engaged in research work.

Health Propaganda

Public opinion was ripe for instruction in matters pertaining to the care of health, health propaganda was becoming increasingly popular. Much of this work was undertaken by men who had had no medical training and was of the nature of "stunts," a great deal consisting of thinly veiled advertisements. There was, therefore, a danger of reaction on the part of the public unless the work was performed by disinterested propagandists trained in the laws of preventive medicine, this could only be done by the enlightened medical practitioner. The most effective educational work was individual instruction given at the psycho-logical moment, and not class teaching this could best be given by the private or "family" doctor. His opportunities for service were undoubtedly great, not only in guiding the patients in the intricate paths of health, but also in assisting the present activities of public health authorities, as in the case of tuberculosis. There was much work to be done in educating the public as to the true value of drugs in the cure of disease.

Dr Howard-Jones then paid a tribute to specialists and research workers for what they had done in advancing the knowledge of preventive medicine and in educating the public. He added that the principle of periodical

medical inspection had long been established in the navy and army, and had been extended to the younger members of the civil population. Its further extension to the general community should naturally follow. It had been recognized by some of the leading American insurance companies that it was cheaper to maintain health than to cure sickness, and there was a growing realization of the importance of health propaganda among British companies. The general public was also beginning to appreciate medical supervision.

INTERNATIONAL SOCIETY OF MEDICAL HYDROLOGY

ANNUAL MEETING IN ENGLAND

(Concluded from page 718)

AFTER two days' conference in London, which constituted the first part of the annual meeting, a party of 105, consisting mainly of members of the International Society of Medical Hydrology from seventeen different countries, accompanied by wives and daughters, started on a tour of the more important English spas.

Visit to Harrogate

The first spa they visited was Harrogate on October 12th. After an address by Dr. FERGUSON on the waters of Harrogate they inspected the baths, and were much interested in the various hydrological measures, as well as in the melted paraffin wax baths for chronic joint diseases. The morning session, held on October 13th at the Royal Bath Hospital, was devoted to the treatment of children in waters and baths. Among the papers were the following.

Dr. A. KELLER described the work done at the Children's Hospital at Rheinfelden (Switzerland), which has 115 beds. The cases treated are mainly the more chronic forms of tuberculosis, lymphatism, and conditions of malnutrition and debility. Good results were obtained from lime baths, which were given two or three times a week for four weeks at a temperature of 97° F. The strength of the baths varied from 1/2 per cent for the more debilitated to 4 per cent for the more robust. It was in general observed that the weaker baths had a more immediate effect, while with the stronger the effect might be delayed to a later stage in the course of treatment.

Professor GROEDL stated that it had been found at the two children's institutions at Nannheim, in which 30 per cent of the patients were suffering from heart disease, that treatment with saline baths of gradually increasing strengths was less fatiguing when combined with CO₂ effervescence.

Dr. SIGMUND WASSERMANN (Frankfurt and Vienna) summarized the fashions through which iron medication had passed, and quoted recent work done by Starkenstein and others which showed that the only therapeutically active form was the instable ferrous iron, thus accounting for the empirical observation that ferruginous waters should be drunk fresh from the springs. Since the metabolism of iron was more easily deranged in children than in adults, he considered that the use of chalybeate waters in anaemic conditions in children might with advantage be further developed. The author had also found good results from ferrous waters in gastro-intestinal catarrh.

Professor STANLEY (Birmingham) described the use of hydrotherapeutic measures as a sedative, and stated that he had found them particularly useful in chorea either in the form of hot packs at 100° F. lasting about twenty minutes in such children as were not frightened by this treatment or hot baths at 98° F. As a gauge of the improvement obtained he made every child write its name and the date in ink on the case sheet daily. The variations in muscular co-ordination could thus be seen at a glance, and improvement became evident in many cases after one or two packs daily for four or five successive days. Though there could be no doubt that hot packs were often effective when drugs failed, a child occasionally became more irrit-

able after a hot pack, it was, however, difficult to compare the results of pack treatment with those obtained from the various drugs which had been used. In discussing the mode of action of the pack in these cases he pointed out that chorea in children was one of the few conditions in which a subnormal temperature might continue for weeks in conjunction with a rapid pulse, indicating a disturbance of the heat-regulating mechanism. It seemed probable, from recent work on the heat-regulating functions of the supranal glands, that both the subnormal temperatures of chorea and the hyperpyrexia of other forms of acute rheumatism might be due to derangement of the heat-controlling functions of the thyroid and suprarenals by rheumatic infection.

Professor CATTANEO described the uses of alkaline and chloro-iodide waters, "pulverized" by the passage of compressed air, in the treatment of catarrhal and other conditions in children. Dr. HINSEN mentioned, among the difficulties of applying spa treatment to children, the fact that there were no suitable institutions for treating small paying patients away from their fussing mothers comparable with those belonging to charitable organizations. A paper was read also by Dr. ANGLADE (La Bourboule) on mineral waters. In the brief discussion which followed the papers Dr. POUTON, referring to Professor Groedel's remarks, suggested that light might be thrown on the problem of CO absorption through the skin in CO baths by estimating the CO₂ content of the mucus secreted during and immediately after the bath.

Dr. J. A. THOMSON (Harrogate) next demonstrated a series of nearly fifty radiograms of cases of osteo-arthritis to illustrate his thesis that the typical and diagnostic lesion of this disease is a cyst-like focus of bone destruction surrounded by a ring of osteo-sclerosis. He had found that these foci were so small in early cases as to be scarcely distinguishable, that they gradually increased in size or number, and that the individual foci were subject to alternating activity and subsidence, thus accounting for alternating periods of exacerbation and relief of symptoms. He maintained that the clinical symptoms depended more on the position of the active focus in relation to a weight bearing or friction-bearing surface than on the condition of the joint as a whole.

Cases of various types of chronic joint disease were demonstrated by the physicians of the hospital, and parties were shown round the wards and baths. It was noted with interest that here, as also in the Devonshire Hospital at Buxton, considerable space is allotted to recreation rooms for the patients, as the importance of this aspect of hospital treatment has not in general received much attention hitherto.

In the afternoon the members of the society visited Mountains Abbey under the guidance of Dr. Moody, the organist of Ripon Cathedral.

Buxton

On October 14th three charabancs took the party to Buxton, where after a short paper by Dr. BROOKLYN on the physical and chemical properties of the waters, visitors were shown round the Thermal Baths and the Natural Mineral Water Baths. The visitors thoroughly investigated the baths, which have been recently rebuilt, and were much interested in the aerated flowing bath, the swimming pools of blue water characteristic of this spa, and the white marble drinking fountain where the glass is dipped and filled fresh from the flowing source.

At a reception given by the Buxton Medical Society Mr. HARRY PLATT discussed co-operation in the treatment of chronic rheumatic diseases between the spa hospitals, the universities, the medical schools, and the treatment clinics which were being started.

On the following day members of the staff of the Devonshire Hospital demonstrated cases of gout, osteoarthritis and rheumatoid arthritis, and described the method used to estimate the radium emanation in the water.

A permanent international society for the study of rheumatism was constituted by delegates from the national committees and societies.

Rheumatism as a national problem was the subject of the final discussion held at Buxton on October 15th, under the presidency of Dr BUCKLEY. Reports were presented by delegates from seven countries. Dr A. ZIMMER (Germany) stated that information on incidence and cost of treatment had been collected covering over one million cases, and it had been clearly shown that though the incidence and invalidity due to rheumatic disease was considerably greater than that of tuberculosis the amount expended on treatment was much less. Dr DALMAY (Hungary) reported that, though in his country rheumatic diseases appeared to be less prevalent than in some others, careful statistics were now being collected, and with the support of the Hungarian Ministry of Health collections of papers bearing on the subject were to be translated and published from time to time. Dr KARLSSON (Sweden) said that in Sweden the most important recent advance had been in training in new occupations during or after treatment of such workers as were unfit to return to their previous employment.

Dr R. FORTESCUE FOX, speaking for the British committee, which was about to give place to a more permanent body, emphasized the value of co-operation between medical and industrial organizations in dealing with those rheumatic problems in which both were interested, this appeared to have been more effectively developed in Great Britain than elsewhere. Dr VAN BUREN (Holland), Dr FURFAYROLLES (France), Dr SARMENTO (Portugal), Dr FROHNE (Wiesbaden), Professor PLATZ (Hamburg), and Mr APPLETON (Federation of Trades Unions) also spoke. Discussing the perennial topic of nomenclature, several delegates agreed that the classification adopted in the English Ministry of Health reports was the most useful that had so far been devised from a theoretical and practical point of view.

In a paper on "A rheumatism clinic," Dr A. R. NELIGAN enumerated the most important problems which faced those who proposed to organize such a clinic in England. He suggested that some reciprocal arrangement with the out-patient and in-patient departments of existing hospitals and close co-operation with the general practitioners sending the cases for treatment was very desirable, and that much thought and care should be devoted to research.

In the afternoon the party drove to Chatsworth, where they had tea at the invitation of the Duke and Duchess of Devonshire. On their return to Buxton Dr BUCKLEY (U.S.A.) read a paper on the hot sulphur springs of Santa Rosalia in Mexico, which contain, in addition to colloidal sulphur and sulphur compounds, a new type of sulphur bacteria belonging to the class *Sulfomonas thiocyanans*, first discovered by Waksman and Starkey.

DRITWICH

On October 16th the party proceeded by road to Droitwich where they were entertained at luncheon in the Salters' Hall by the Corbett trustees, the present proprietors of the spa. Hospitable speeches were made by Mr Jacobus Hood on behalf of his co-trustees, by the mayor on behalf of the municipality, and by a former mayor, Mr Percy Pond, who addressed the visitors in French, German, Spanish, Portuguese, and Italian. Dr Malcolm Campbell welcomed them in the name of the medical profession of Droitwich, and Dr Percy Roden gave a brief address on the local brine treatments. They were then conducted in four parties round the St Andrew's bathing establishment, where demonstrations were given of the uses of natural brine baths, more particularly in chronic rheumatic disorders. It is of some interest to recall here that one of the first medical men to draw general attention to the possibilities of Droitwich brine baths in rheumatism, sciatica, and gouty arthritis was Sir Charles Hastings, founder of the British Medical Association, who practised in the neighbouring city of Worcester.

BATH

The tour ended with a visit to Bath. The members of the society and their friends were welcomed in the Pump Room on October 16th by the mayor, Alderman Cedric

Chivers, the mayoress, Madame Sarah Grand, being absent through illness. The director of the hot springs of Bath, Mr John Hatton, addressed the guests on "The Baths of Bath throughout the Ages." He believed that the springs must have been used by man for some 10,000 years, especially by the peoples who erected the stone monuments at Stonehenge and Avebury, and the lake villages at Glastonbury and Meare. But the earliest legend of a cure at Bath was associated with the name of Bladud, the leprous son of King Lud Hudibras, in 863 B.C. Mr Hatton described the foundation of the Roman baths from A.D. 55 onwards, their destruction and subsequent restoration by the Saxons, and the great revival of Bath as a place of healing under John de Villula, first Norman bishop of Bath and Wells. In 1542, on the dissolution of the monastery, the control of the baths passed to the city, and in the eighteenth century they were reconstructed by John Wood the younger. During the sixteenth century publication of treatises on the curative effects of the waters began, together with sundry speculations on the cause of the heat of the water. Pepys, in 1668, had qualms because it could not "be clean to go, so many bodies together in the same water." At that time mixed bathing was still in vogue. Mr Hatton called attention to the brass rings, bearing the names of donors and inscriptions, affixed to the King's bath as votive offerings during the seventeenth and eighteenth centuries, and used for bathers to hold. He concluded his address by recalling the revival of drinking of the waters in 1663, and the establishment of the first Pump Room in 1704.

Dr J. M. H. Munro described investigations he had recently undertaken on the radium content of the waters, researches which had just been published in a pamphlet. He illustrated his remarks by lantern slides showing the methods of measurement of radon in the water, and by placing an emanation chamber in an epidiascope and filling it with gases from the spring he demonstrated on the screen the fall of the electrified gold leaf of an electro-scope to complete collapse in less than thirty seconds. He pointed out that the highest value of dissolved radium found in the mineral springs of Canada reported on by the Government was 46 units per litre, while 138 units were found by Ramsay in the King's Well water. All patients who drank the waters and took baths in bath-rooms of moderate size, and to a less extent those who used the swimming bath and the Pump Room, were taking in radon in the water they drank and the air they inhaled. Dr Munro's pamphlet contains an account of radium, and an interesting summary of the researches he has carried out at Bath.

On October 17th the visitors were received in the Pump Room by Dr Rupert Waterhouse, who described briefly the advantageous situation and climatic conditions of Bath—the three springs—the Cross, the King's, and the Hot—with temperatures ranging from 104° to 120° F., the mineral contents of the water, and the chief disease for which it was used. Demonstrations were then given to parties of the guests of the various methods of treatment given in the baths. The foreign members of the society were impressed by the wide range of baths and apparatus available, including the deep baths of 300 to 500 gallons which are a specialty of Bath, Aix, and Vichy donches, whirlpool and Nauheim baths, mud packs of volcanic deposits from the neighbourhood, Plombières treatment, and every variety of electric, Greville, and radiant heat bath. At the Royal Mineral Water Hospital cases were shown by Drs Waterhouse, Gordon, Lindsay, Vincent Coates, and Gordon Watson. Dr Waterhouse demonstrated various forms of spondylitis. Dr Coates had chosen cases to illustrate his view that arthritis was often a matter of systematic and not of focal infection. Dr Watson showed patients whose chief symptom, loosely described as sciatica, would be better termed sciatic pain.

The members of the society were entertained at luncheon in the Guildhall by the mayor of Bath. In reply to the toast of "The Visitors" speeches were made by Professor Sarmiento of Portugal, Dr Keller-Stophang of Switzerland, Dr Schmidt of Czechoslovakia, and Dr Takayasu of Japan. The afternoon was spent in viewing the sights of Bath and visiting the Roman baths.

British Medical Journal.

SATURDAY, OCTOBER 27TH, 1928

AUTHORITY IN HEALTH PROPAGANDA

THE personal factor has in all ages played a considerable part in determining the success or failure of schemes and enterprises. Movements which have attained wide vogue have often derived their impetus as much from the character of their originators as from their own actual or reputed merit. The authority with which the leader stated his tenets and pointed the course of action was quite as effective as his reasonings or his arguments. It is therefore not surprising if in relation to health propaganda—a modern movement which rivals in importance many good enterprises of the past—some hold that the mind of the public is prone to respond to personality at least as readily as to argument. But while even an easily demonstrable truth is more assured of acceptance if taught by those who speak with accepted authority, there is a little danger that the appeal on the grounds of personality may sometimes be used as a substitute for the appeal to reason and understanding. If the health propagandist can produce in the people a settled disposition towards healthy living it may seem to matter little whether his object is attained by his personal influence, the cogency of his reasoning, or a judicious combination of both. In an ideal world the appeal to reason would suffice, but, human nature being what it is, the unpalatable fact must be faced that a capacity to exploit personality and invoke authority is not, and never has been, necessarily allied to the strictest regard for scientific truth.

The medical practitioner of this country appears to be well entitled to speak with authority on the subject of health and its attainment. It is said by Dr W. W. Jameson, in his address which we print elsewhere in this number (p. 733), that for the dissemination of health knowledge among the public no one has a greater opportunity than the general practitioner. He meets these opportunities every day in his practice. And other avenues are opening. The Industrial Health Educational Society, for example, has enlisted the services of the medical man to give health lectures to workpeople. The ordinary man or woman feels that as a doctor he understands his subject, and is ready to accept his teaching accordingly. But such teaching is likely to remain longest in the memories of those who have grasped the reasons underlying it, even though the reasons pass out of consciousness.

In order that the doctor may play a worthy part in the health movement of the time, as every doctor will desire to do, it is essential, as Dr Jameson points out, that during his training as a medical student his mind should be focused upon the preventive aspects of medicine in general and that he should be made acquainted with the organization of the health services of the country, with the duty he will owe to local public health authorities, and with the

help he may expect from them in return in the conduct of his profession. Of the preventive aspects of medicine it may be said that the best teachers have not failed to insist upon them, and that at the present time these aspects are thrown into high relief by the plans for the reconstruction of the teaching of midwifery, already inaugurated by some medical schools and in course of adoption by others. The methods for controlling maternal mortality, the teaching of which constitutes the primary object of these changes, are an impressive lesson to the student. He is taught not so much how to apply the forceps as how to obviate their use, not so much how to treat puerperal sepsis as how to prevent its occurrence. He is taught in the ante-natal clinic to seek and remedy those conditions which, left untreated, will lead to prolonged or difficult labour. This experience conveys to his mind a vivid picture of the uses of prevention, and suggests the question, "Why not prevention in other fields?" The practical importance of instructing the student in the organization of the health services of the country is almost too obvious to need emphasis. Care, however, should always be taken to link up administrative and other measures with the fundamental scientific principles whether of chemistry, bacteriology, physiology, or pathology, on which they must ultimately rest. The minutiae of 'jointing' lead pipes to stoneware are not of medical interest, but the general medical practitioner as an expert in health to whom his fellow citizens will turn for guidance, should know something, say, of water purification, and if he does not learn it as a medical student he is unlikely to learn it at all.

The ante-natal clinics, the maternity and child welfare clinics, and like undertakings with which they are usually associated, are invaluable centres of propaganda, not only for the health of mothers and infants, with which they are immediately concerned, but also for health in general. The views of the "welfare," as these institutions are familiarly termed by their clients, are freely sought and usefully given on health questions of all kinds. Many of these centres do not confine their educational work to direct instruction of the individual patient by the medical, nursing, and health visiting staffs. They hold classes in such subjects as infant care and elementary physiology, and help thereby to lay the foundation of understanding with which unhygienic practice is incompatible. Even in schools, where authority is bound to play a part in all education, it is wise as early as possible to correlate the authoritative inculcation of good habits of living—which to the child are sure to appear as somewhat arbitrary, if not actually unpleasant—with elementary instruction in the principles of hygiene. The child is a creature that asks the reason why, and this characteristic may be usefully exploited throughout his education.

Dr Jameson says that there are over fifty societies now engaged in health propaganda in England. A considerable number of these, in so far as they strive to teach the principles of health and not merely to exploit the personality of those who voice their views, may be commended as doing work of great value to the public. Many, however, will agree with

the statement made by Sir George Newman in his Annual Report on the State of the Public Health, of which our first notice appears at page 753, that 'this excellent work does not, however, absolve the local authorities from their responsibility to co-ordinate and supplement, and if necessary lead.' Neither, we may add, does it absolve the private practitioner, who, more than anyone else in the country, is fitted by his special experience to lead the public to a knowledge of the scientific facts on which all preventive medicine is grounded. 'Without the consent and intelligent participation of the individual,' says Sir George Newman, 'the efforts of the State in their behalf must of necessity fail to reach their goal.' Consent may be obtained by authority, but only by reasoned health propaganda can the desirable combination of consent and intelligence be assured.

MATERNAL MORTALITY IN AUSTRALASIA

THE final report of the Director of Obstetrical Research in Victoria and the last report of the Director of Health in New Zealand show that the Antipodes have the same heart-searchings as ourselves over their maternal mortality. The Victorian Branch of the British Medical Association anticipated the parent body, for it set up a committee to investigate puerperal mortality six months earlier than the Association at home, and its report appeared three years (March, 1925) before the English final report (April, 1928). One consequence of the work of our Victorian colleagues was a benefaction of £10,000 for the investigation of the causes of maternal mortality and morbidity throughout the State and to suggest means to lessen the same. Under the terms of this bequest an Obstetrical Research Committee was appointed, and Dr Marshall Allan was chosen as Director of Research. Dr Allan's final report was issued this summer, and adds confirmation to the conclusions of the English and Victorian committees.

All three reports make suggestions as to the better obstetrical training of medical practitioners and midwives, better hospital provision and ambulance facilities for difficult cases, and further research into the causes of puerperal sepsis and toxæmic states. Each lays emphasis also on the importance of antenatal supervision in order to lessen complications in pregnancy and labour. These conclusions must receive general acceptance, but the thorny problem of putting them into practice and of bringing about a lessening of maternal mortality seems no nearer of attainment, and the New Zealand report says that 'in spite of the very active campaign for the reduction of these deaths the rate of 4.91 per 1,000 live births represents an increased rate on the preceding year.'

The lowering of the maternal mortality has proved much more difficult than that of the infantile mortality—the one with which it is so often compared, and behind which it lags so far. A rate of over 150 infants dying in the first twelve months out of every 1,000 births registered left much more room for improvement than a death rate of less than 5 mothers for every 1,000 live born children. The infantile death rate is due to simpler causes and calls for simpler measures than deaths in labour, for in obstetrical work the rapid changes make all difficult labours into emergency cases. Besides calling for sound judgement, these complications are too occasional in the practice of most individual doctors to allow of any but those with hospital appointments to acquire a wide experience of

them. General improvement in hygiene, which has done much to reduce infantile mortality, seems to be a factor of far less moment in maternal mortality, and our knowledge of the etiology of the two largest elements—sepsis and toxæmic states—is still insufficient. The striking drop in the infantile mortality during this century is largely attributable to the education of the mothers and the effort to return to physiological methods, natural feeding, and a more natural life with free access to fresh air and sunlight so far as this is attainable. The lesson is still to be learnt in midwifery practice that the primary object in Medicine should be more closely followed—that of securing the physiological throughout pregnancy and parturition. Education of the child-bearing woman will also be required, for the call of the patient for intervention in labour is too insistent to be resisted by the practitioner, and thereby the physiological becomes more difficult of attainment.

This point, in so far as assisted delivery is concerned, receives full attention both in the report of the Director of Obstetrical Research in Victoria and in a special contribution to the New Zealand report by Dr Henry Jellett, formerly Master of the Rotunda Hospital in Dublin and now consulting obstetrician to the Dominion Department of Health. In the former document a forceps rate of under 30 per cent is regarded as not unreasonable in private practice based on the result of interviews with individual practitioners (633 in all) throughout the State. From the same evidence it appears that the rate is lower in the country districts, increases in the larger towns, and reaches its zenith in Melbourne, where it is higher in the residential than in the industrial areas. Personal impressions, however widely obtained, are not good evidence, and were rejected by the British Medical Association Committee in this country. Dr Jellett regards 6 per cent as a forceps rate which ante-natal care and a sound management of the first and second stages of labour render possible without unnecessary suffering or injury to mother and child, and he ascribes an unduly high rate to obstetrical inexperience and to pressure by the patient's relatives. The difference in the class of practice is not taken into account, though that more than anything else makes it impossible to lay down a flat rate. New Zealand hospitals show a steady decline in the institutions as a whole, a lessened forceps rate in the larger more than balancing an increasing rate in the small hospitals. In two years the rate in the hospitals has dropped from 14.3 to 12.5 per cent. One of the concluding remarks of Dr Jellett's report is that 'the public should remember that to the unavoidable consequences of disease and deformity, and of the sometimes avoidable consequences due to insufficient medical or nursing education, there must be added the wholly avoidable misfortunes resulting from misguided and clamorous relations, neglected advice, and unsuitable surroundings.' Although he mentions the need for educating the public he scarcely stresses this point, yet a change in the attitude of patients and their relatives towards labour would appear to be necessary to more physiological child bearing.

One thing clearly brought out by a study of these investigations by committees is that the results achieved by such inquiries are not likely to be commensurate with the time, trouble, and expense involved. Nevertheless, the committees have served a good purpose in showing that many factors go to maintain maternal and infantile wastage and that it is the pursuit of no single factor, but an advance in all directions, that will lead to gradual improvement.

INTERNATIONAL CONGRESS OF MILITARY MEDICINE AND PHARMACY

UNDER the patronage of the King the fifth International Congress of Military Medicine and Pharmacy will be held in the Great Hall of the British Medical Association next year, from May 6th to 11th. This congress owes its origin to the inter-allied surgical conferences which were held during the war with a view to deriving the utmost benefit from the knowledge gained by each of the allied countries as regards the treatment of wounds. The Belgian Army Medical Service, realizing the value of such conferences in times of peace, took the initiative by summoning, in 1921, an International Congress of Military Medicine and Pharmacy, at which twenty nations were represented. This was followed two years later by a congress in Rome, a third in Paris in 1925—when forty nations co-operated—and a fourth at Warsaw in 1927, which attracted the delegates of thirty-two nations. The subjects to be discussed at the forthcoming congress are the evacuation of the sick and wounded by water and by air, together with the role of the medical services in combined operations, tropical fevers of short duration, wounds of blood vessels and their sequelae, the physical and chemical analysis of glass and rubber articles employed by the medical services, and the standard of dental and physical fitness in the various military services. In connexion with the congress there will be an exhibition of medical and surgical equipment, and visits will be paid to stations of the three fighting services. The president of the organizing committee is Lieut-General Sir Matthew Fell, Director-General of the Army Medical Services, and the secretary is Major A. D. Stirling, R.A.M.C., The War Office, S.W.1. Medical officers, dental surgeons, and pharmacists who belong or have belonged to the forces of all members of the League of Nations are invited to the congress, and also officers of organizations in association with the medical services. The subscription is fixed at 10s. for men and 7s. 6d. for women, this entitles the subscriber to copies of the official reports and participation in the official excursions and receptions. Those who wish to attend are asked to notify the secretary as early as possible before January 1st, and, at the latest, by February 1st. Railway companies in Great Britain and Ireland have agreed to issue tickets at reduced fares.

THE DELINQUENT PERSONALITY

THE literature of child psychology, educational psychology, the psychology of the delinquent and the criminal, grows apace. In a relatively new study, with an increasing tendency to devote itself to immediate practical application, there can be very few publications on these subjects which do not contain some facts or suggestions of real importance, but that the value of a volume is not in proportion to its size is illustrated by two books now before us. One is a little work by Dr R. G. Gordon in the well-known To-day and To-morrow Series, entitled *Autolycus, or the Future for Miscreant Youth*¹, the other is *Emotion and Delinquency*² by Dr L. Grimmer, a volume in the Library of Educational Psychology. The former is a setting-out of English thought and it presents a stimulating general survey of the whole subject, the latter is, in the main, a series of American examples. The aims of the two books are no doubt not identical, though they are very similar, and each may be said to fulfil the purpose of its author and publisher, yet of the two it is in Dr Gordon's booklet that the growing public interested in this branch of social psychology and action will find more of help, of direction,

and of practical value. The one objection that can obviously be raised to it is the use of the word "miscreant" in its title: this is perhaps a concession to the series in which it appears. The word is much too strong. The most authoritative of dictionaries gives its meaning as an adjective "depraved, villainous, base," and as a substantive "a vile wretch." "Delinquent" is much better. Each book is a valuable attempt to enable us to understand the youthful delinquent, and, through understanding, to discover what can be done by the doctor, the teacher, the parent, the social worker, and the public in general to help the child, the adolescent, the youth whose make-up and environment put him or her in a position of danger. Dr Gordon's basic thesis, here as in his other writings, is that personality includes the relationship of the individual to his environment, and that as regards the unstable personality "the neurotic is characterized by conflict within the ego between the various impulses which go to make up the individual himself, while the delinquent is characterized by conflict between the ego and the environment." The delinquent often is neurotic, but this is not necessarily so. Unless, however, this underlying factor, the peculiarity in the personality of the delinquent, is recognized, studied, and allowed for (since its elimination must be regarded as remote), the removal or improvement of secondary factors of influence, such as those connected with physical health, housing conditions, opportunities, and provocation, may well prove to be profoundly disappointing. In a series of short but extremely interesting and suggestive chapters Dr Gordon goes on to discuss the social factor, the educational factor, the psychological factor, the medical factor, and the aims of the future in dealing with each and all of these. He stresses, of course, the fact that it is the child's emotions even more than its intelligence that need attention and adjustment. In the home "a child should be reared as part of an equilateral triangle. Mother and father should both exert their influence from a different but an equal angle, neither ousting the other in affection or regard, and remembering that the child is also an equal, neither to be repressed into submission nor adulated into ascendancy." Thus the illegitimate child, the orphan, the child in a jarring household, are obviously in special danger and need. In the school both the backward and the intellectually precocious require particular attention, and "the teacher will realize the responsibility which he holds in respect of the emotional development as well as of the intellectual development of the child," and that "each child has his own impulses, ambitions, and capabilities." The appointment of skilled psychologists by educational authorities to help the teachers, and the parents, in their difficult task is likely to be a great advantage. Certain children also "show asocial behaviour which is directly or indirectly traceable to states of bodily or mental health which come within the purview of the physician." Consequently in dealing with the problem "the doctor must have a place, but he must be a man of wide experience, and above all be free from preconceptions and prejudices." These are but indications of the wide field which Dr Gordon surveys, and his book will be found full of information, stimulus, and suggestion to all concerned. Small in compass, it is rich in wisdom. Dr Grimmer's book is, by contrast, rather a clinical study of some five hundred delinquent individuals from the New York Neurological Institute—all females. From the standpoint of a medical man he investigates the heredity, the family history, the physical and mental states, the environment, of these cases, and draws a few general conclusions. He deals with the power of the emotions as against control by the intelligence in these instances of social misbehaviour, but seems to regard intellectual defectiveness as a more prevalent and potent factor than does Dr Gordon, he attaches considerable importance to endocrine disturbance as constituting

¹ *Autolycus or the Future for Miscreant Youth*. By R. G. Gordon M.D. D.Sc. F.R.C.P. Ed. To-day and To-morrow Series. London: Kegan Paul Trench Trubner and Co. Ltd. 1928. (Pcap. 8vo. pp. 94. 2s. 6d. net.)

² *Emotion and Delinquency*. By L. Grimmer M.B. Library of Educational Psychology. London: Kegan Paul Trench Trubner and Co. Ltd. 1928. (Ocm. 8vo. pp. ix + 147. 7s. 6d. net.)

a genuine organic inferiority in the case of most, or many, delinquents. The difficulties of racial adjustment, too, are naturally prominent in the cosmopolitan conditions with which Dr. Grimbarg deals.

HEALTH ACTIVITIES OF THE LEAGUE OF NATIONS

AN interesting survey of the scope and character of the Health Organization of the League of Nations is given in the agenda prepared for its governing body—the Health Committee of the League—at its meeting this week in Geneva. After considering various resolutions and decisions of the Assembly and Council affecting its work, the committee will apply itself to the question of co-operation with Latin America, and will have before it reports of the various health commissions and conferences which have met since its last meeting. Commissions are at present engaged upon studies of malaria, cancer, small pox, and vaccination at the committee's behest, while the conferences under its auspices consist of experts in child welfare, the sero-diagnosis of syphilis, and anti-tuberculosis vaccination. Certain aspects of the opium question, notably the application of the articles of the Convention of 1925 regarding products to be added to or withdrawn from the list of drugs covered by the Convention, will also come under review, and cognizance will be taken of sanitary conditions in Greece and other countries in connexion with the recent dengue epidemic. Before the meeting of the parent body the committee on syphilis—to be attended by experts from Germany, Great Britain, France, and the United States—will meet to discuss modern methods of treatment, the durability of the clinical results obtained in connexion with the apparent recrudescence of syphilis in certain countries, and the training of doctors in modern methods. An anti-tuberculosis congress was held at the Pasteur Institute in Paris on October 15th, to establish the best methods of demonstrating the immediate and deferred results of BCG vaccination on laboratory animals, cattle, and human beings. The organization of this congress affords a good example of a method often adopted in such matters in connexion with the health work of the League—a method which might be described as the internationalization of expert opinion. Three sub-committees, composed of bacteriologists, clinicians, and veterinary surgeons respectively, studied the question. The bacteriologists included British, American, German, Austrian, and Russian experts, the clinicians were drawn from France, Norway, Austria, Italy, Spain, and Germany, the veterinary surgeons from Italy, Holland, Poland, and France. Representatives of eleven different countries were therefore co-operating in the work. The Mandates Commission of the League will also meet at the end of this month, and among the items on its agenda is the subject of public health in mandated territories.

THE NATIONAL INSTITUTE FOR THE DEAF

THE work of the National Institute for the Deaf, a body which was constituted in its present form some four years ago, appears to have received comparatively little support from the public, despite the magnitude of the task which it has undertaken and the evident inadequacy of the existing machinery for the care of the deaf. In the report of the Institute for the year ended March 31st it is suggested that deafness, except by those affected by it and their immediate associates, is of all afflictions the least understood, and that it is consequently difficult to arouse interest in the deaf and their problems. According to this report there are some 40,000 deaf-born persons in the country who depend for assistance from the age of 16 almost entirely upon voluntary agencies, State provision is

made for their school education, but after its completion the authorities take no cognizance of the fate of the deaf. In addition to the deaf-born there are large numbers of persons who have become deaf at later stages in life, but who also need assistance and advice. The Institute has, through members occupying seats in the House of Lords, endeavoured to enlist the sympathies of the Government, with, it appears, little success, and the necessary work will therefore remain in the province of voluntary effort. One of the first tasks undertaken on the reorganization of this society a few years ago was a survey of the existing machinery, followed by a conference of the various bodies interested in the welfare of the deaf, and by the promotion of measures to secure more effective co-operation among them. The report shows that societies for the care of the deaf and dumb are in operation in some fifty districts—often with totally inadequate resources in workers and money—while in large areas no such agencies exist, with the result that probably half the deaf and dumb are receiving no assistance whatsoever. In its effort to secure the national organization of the work the Institute's policy is to promote the establishment of counties associations for the deaf, covering the whole country in seven districts, and composed of representatives of Education Committees, Poor Law authorities, voluntary schools and welfare societies, and persons specially interested in deafness. Such associations have already been established in Scotland, and for the northern and midland counties in England. It is hoped that these bodies, by securing the co-operation of parties who have hitherto worked independently of each other, will gain the support of the public and make possible a much more effective system. The problem of securing employment presents special difficulties both to the deafened and the deaf-born, and there is an urgent need for training facilities and for some means of securing their entrance into industry in occupations suited to their conditions, facilities are also required for their higher education. Among the Institute's auxiliaries is a useful and active medical committee, which includes several nurses and others possessing special knowledge of the needs of the deaf, the committee endeavours to prevent deafness by the dissemination of advice as to the need for early treatment of diseases likely to cause it, and for the entire avoidance of panaceas advertised by unqualified persons. It is suggested that the inclusion of specialist treatment in ear, nose, and throat troubles as an additional benefit under the national health insurance scheme would doubtless have an important effect in preventing deafness, representations have been made on this subject to the Ministry of Health. Only a few approved societies, it has been found, provide, or assist in providing, aids to hearing for their members as an additional benefit, and the Institute urges that all societies should consider the advisability of doing so. In this connexion it may be noted that the Institute has issued a warning against the indiscriminate purchase of electrical aids to hearing, urging that deafened persons should invariably consult an aural specialist, at an ear hospital or privately, and be guided by his advice as to whether an instrument is likely to be of use. If the advice is favourable deafened persons should deal only with firms which allow a home trial of two or three weeks before purchase, or which agree otherwise to meet them considerably if the instrument fails to be of service. The financial position of the Institute, we regret to note, is unsatisfactory, the ordinary income last year was only £1,025, and it was necessary to draw upon the sum of £1,491, raised by a special appeal, to meet the expenditure. As a result it was impossible to initiate the provision desired for the care and training of blind-deaf infants, the industrial training of deaf and dumb adolescents, the care of mentally defective deaf, and the employment of the deaf.

DIPHTHERIA IMMUNIZATION THE QUEENSLAND FATALITIES

WE have now received the full text of the report of the Royal Commission of Inquiry into the fatalities which occurred at Bundaberg, Queensland in January last. An outline of the findings of this Commission was given in the *British Medical Journal* of June 23rd (p. 1076). The report,¹ which has been published by the Government of the Commonwealth of Australia, is a document of very considerable scientific interest. In addition to a narrative of the events that followed the inoculation of children with a diphtheria toxin antitoxin mixture, there are now made available details of the clinical histories, an analysis of the symptoms and a careful discussion of their significance. The pathological investigations as reported in length, and the considerations which led the Commission to incriminate a pathogenic staphylococcus are fully recorded. In thirty-one appendices to the report the various steps of the inquiry are set out in detail. The wide range of possibilities entertained and excluded only after elaborate consideration is particularly noteworthy and it is clear that the utmost care was taken to arrive at a correct verdict. Examination of all the available evidence points to the injection of living staphylococci as the cause of the deaths at Bundaberg. There can no longer be any doubt that these regrettable fatalities were accidental, and that such an accident is most unlikely to happen again. The Commissioners declare with emphasis that active immunization is the only specific measure at present known for the control of the incidence of diphtheria, and that there is no inherent danger in its practice when properly controlled.

THE DIETETIC TREATMENT OF INFANTILE DIARRHOEA

It has been shown that infantile diarrhoea may occur on a diet of sterile milk if the quantitative and qualitative composition exceeds the limits tolerated by the infant. An increased motor and secretory activity of the bowel ensues, and the pH of the different sections of the gut alters, with the result that organisms normally present and harmless in one section migrate to another, and there become pathogenic, thus constituting an endogenous infection. Professor L. Moll² believes that this is a more frequent cause of diarrhoea in infancy than exogenous infection. Hence, apart from any aperient action which they may have, antibacterial remedies (such as calomel and salol) are unlikely to be effective as intestinal disinfectants since they will inhibit the growth of physiological as well as pathological organisms. At the beginning of treatment in a case of infantile diarrhoea Moll withholds food for a maximum period of twenty-four hours, giving only water or tea. He considers that this period should be as short as possible in view of the risk of acidosis if there has been much vomiting; moreover, the sick infant is unable to retain water in the tissues, since the metabolism of mineral salts is deranged and an excess of these salts is being excreted. He therefore recommends that a "stabilizing" diet should be substituted as soon as possible. This must contain enough water, salts, and other constituents to make up for the dehydration which has occurred and to arrest the loss of weight as quickly as possible. Its caloric value should approximate to that of human milk, and at the same time it should be readily digestible. Human milk, even where procurable, was found unsuitable for this stabilizing diet because of its low salt and protein content since the loss of protein in infantile diarrhoea is high it must be replaced as quickly as possible. The addition of calcium whey

(prepared by adding 4 grams of calcium lactate to 1 litre of warm skimmed milk and then boiling and filtering) containing lactose, calcium salts, and 0.3 per cent protein was found very useful. For older infants a mixture of biscuit flour or rice, with water, salt, sugar, sodium bicarbonate, and beaten yolk and white of egg, was first steamed, then pounded and passed through a sieve, and used to thicken either tea or calcium whey. This has the advantage over other flour mixtures that the low protein content is supplemented by the egg, and the method of preparation ensures that a large surface of the particles of flour is accessible to the gastric juices. An almond whey mixture was also used with success, it was either added to human milk or given with one of the cooked flour mixtures. This almond milk whey resembles human milk in its proportions and caloric value, it has, however, a higher percentage of ash, contains added flour and vegetable instead of animal fat, with a lower melting point. All these diets increase the acidity of the stools, which are usually alkaline in the diarrhoeas of artificially fed infants. The infants were kept on one of these diets for four to eight days, and were then placed on a normal diet again or on the one they were taking before the illness. Since this method of treatment was adopted at an institution for maternal and infantile welfare in Vienna, the mortality from infantile diarrhoea has fallen from 32 to 5.1 per cent.

GENERAL MEDICAL COUNCIL BY ELECTION

VOTING papers in connexion with the election of two direct representatives on the General Medical Council were issued on October 20th to all practitioners having registered addresses in England and Wales. Any such practitioner who has not received a voting paper, whether he wishes to vote in the election or not, should immediately communicate with the Registrar of the General Medical Council, 44, Hallam Street, Portland Place, London, W.1, in order to ascertain that his address is correctly entered in the *Medical Register*. Voting papers must be returned so as to reach the Registrar on or before Monday next, October 29th. The joint election address of Dr J. W. Bone (of Luton) and Dr E. K. Le Fleming (of Wimborne) appeared in the *Supplement* to our issue of October 13th. These two candidates were chosen for support by the British Medical Association at the Annual Representative Meeting in July last.

THE Bradshaw Lecture on pyelitis and pyelonephritis will be given before the Royal College of Physicians of London by Dr A. G. Gibson on November 1st. Dr G. F. Still will deliver the FitzPatrick Lectures on the history of pediatrics to the end of the sixteenth century on November 6th and 8th. The lectures will be delivered at the College, Pall Mall East, S.W., at 5 p.m. on each day, and any member of the medical profession will be admitted on presentation of card. The Lloyd Roberts Lecture on Faraday's diary will be given by Sir William Bragg, K.B.E., F.R.S., at the house of the Royal Society of Medicine, 1, Wimpole Street, W.1, on November 29th at 8.30 p.m. Tickets of admission can be obtained on application to the secretary.

THE nineteenth annual exhibition of electrical, optical, and other physical apparatus arranged by a joint committee of the Physical and the Optical Societies, will be held on January 8th to 10th at the Imperial College of Science and Technology, South Kensington. As on previous occasions it will include a trade section and a research and experimental section. The committee invites offers of exhibits illustrating the results of recent physical research, lecture experiments and historical exhibits in physics will also be welcome. Offers should be communicated immediately and in any case not later than November 14th, to the Secretary, Physical and Optical Societies, 1, Lower Gardens, Exhibition Road, London, S.W.7.

Nova et Vetera.

FLORENCE NIGHTINGALE AND NURSING IN FEVER HOSPITALS

A DISTINGUISHED member of the British Medical Association has presented to the collection of autographs in the Library an interesting holograph letter from Florence Nightingale, written in December, 1893. Dr E. W. Goodall, to whom the letter was written, is well known as an authority on infectious fevers and as a former medical superintendent of fever hospitals. It was in that capacity that he sought the advice of Miss Nightingale on questions of nursing fever patients. In a letter to us covering his gift Dr Goodall writes as follows:

The occasion of its (Miss Nightingale's letter) being written was as follows: I was bringing before the Committee of the Eastern Hospital, Homerton, a scheme for improving the nursing service and for keeping up a steady supply of suitable probationary nurses. One of the members of the Committee was the Hon. Maudo Stanley. She was able and kind enough to give me an introduction to Miss Nightingale.

In reply to Dr Goodall's request for an interview he received the following letter:

Dec. 28/93
10 South Street
Park Lane W

DEAR SIR

I shall be much pleased to see you on Saturday afternoon at 4 to 5, as you kindly propose. But it will be to receive information from you, which I know your kindness will give me, before a receipt for the 'best method of training Nurses for the Hospital of Met. Asy. Board' can be worked out—or indeed even its A B C.

You possibly may have a copy of the Blue Book (many years old) on 'Cubic Space in Workhouse Infirmarys' which contains a good deal besides 'cubic space'—and in it they have printed a paper which I was desired to write for them and which contains some of the A B C of nursing in these Infirmarys. It is called 'Suggestions &c.' I have not a single copy left. But I would try and get one for you, if you would wish to see it and have it not already.

Pray believe me

Most faithfully yours

FLORENCE NIGHTINGALE

Dr Goodall continues

I visited Miss Nightingale at the appointed hour. She received me most kindly, gave me upwards of an hour of her time and entertained me to tea. But I experienced a surprise and also to tell the truth, a disappointment. I was ushered into a large room upstairs and was greeted by a small, at any rate small looking lady who was sitting up in a very big bed. She was distinctly well nourished and appeared to me to be in good health. She was, I believe, confined to her room, if not to her bed for some years before her death. She was fully dressed in some black material so far as the clothes which appeared above the bed linen were concerned. On the wall behind her and the head of the bed was a shelf which ran the whole width of the bed and was full of books, to one or two of which she referred in the course of the interview. The surprise lay in the contrast between the almost plump little woman I saw before me and the slim figure of the Lady of the Lamp with which the pictures and statuettes had made me so familiar. As for the disappointment, well so far as I could judge from an hour's conversation, she was not conversant with and therefore did not understand the attitude of the nursing profession at that time (1893). If she was not back to, she was looking wistfully back to, the days when a woman took up nursing as a sacred duty towards suffering humanity and not as a means of earning a living in however honourable a way. But Miss Nightingale had then and had had for many years only second hand information concerning the rank and file of the nursing profession. Consequently, though she gave me some excellent counsel on the general question of hospital nursing I do not think she helped me much in respect of the feasibility of my scheme.

In Miss Nightingale's letter, and in the pleasing word-picture drawn by Dr Goodall, we can find no likeness to the arrogant and tyrannical lady who ordered A. H. Clough about and sent him on errands, as depicted by the satirical

pen of Mr. Lytton Strachey in his *Eminent Victorians*. She lived till 1910, dying at the age of 90, full of honours, which included the Order of Merit, and having earned the respect and even the affection of millions.

THE AUSTRIAN LIP

In a well known passage of his autobiography Edward Gibbon wrote "Our immortal Fielding was of the younger branch of the Earls of Denbigh, who draw their origin from the Counts of Habsburg, the lineal descendants of Eltzeo in the seventh century Duke of Alsace. The successors of Charles the Fifth may disdain their brethren of England, but the romance of *Tom Jones*, that exquisite picture of human manners, will outlive the palace of the Escurial, and the imperial eagle of the house of Austria." Unluckily the romantic legend of the common origin of the Teutings and the Habsburgs has been destroyed by the researches of the late Mr. J. H. Round, but this noble tribute to the genius of Henry Fielding remains in untarnished splendour. The prophecy has in part been fulfilled, for although the palace of the Escurial seems likely yet to outlast many centuries, the imperial eagle has taken wing into the limbo of lost causes and has gone, as a national emblem 'for good,' while *Tom Jones* is still reprinted and delights successive generations of readers.

There is, however, a characteristic of the house of Habsburg, to which Gibbon did not allude, which seems to be as persistent as its coat of arms or its Spanish palace. This is that combination of traits of feature which is known as the Habsburg lip, from the fact that a prominent or hanging lower lip is the most obvious of the peculiarities which constitute this family type.

In an elaborate study of the heredity of the stigmata of degeneration Dr. V. Galippe de Paris published in 1905 a well documented research dealing chiefly with the house of Habsburg and its origins.¹ He showed that the peculiarity of the Habsburg lip depends principally on a disproportion and want of adaptation between the upper and lower jaws—that its subjects are underhung, in fact—while at the same time there is a lateral compression of the mandible which tends to render the angle between the two horizontal ram more acute than normal. This deformity French anatomists call *inferior prognathism*. It must not be confused with the prognathism which is a character of the lower races of mankind and which involves a projection of both jaws beyond the vertical line of the ideal orthognathous skull. Without attempting to follow all the footsteps of courtly genealogists who have professed to find the roots of the Habsburg family tree in the year 690, Dr. Galippe goes back to the fourteenth century and begins with a traditional portrait of Ernest I, Duke of Carinthia, which he says shows inferior prognathism. This is succeeded by some 250 portraits, the series only ending in quite recent times and including the unfortunate Archduke whose murder started the world war. In nearly all these portraits, among which are included those of our Stuart kings, Dr. Galippe sees inferior prognathism, in many cases where it must be confessed that a less enthusiastic observer would only see that fullness of the lips which some artists gave to their sitters as a beauty. Dr. Galippe is on firmer ground when he argues that a deformity such as that shown by the Emperor Charles V has been perpetuated by the inbreeding which has been carried to such a pitch by his descendants and collaterals, although few of them showed the peculiarity in so marked a degree as he did, yet it appeared in an extreme form in the Emperor Leopold I (1640-1705), and as late as 1817 in the Archduke Albert Frederick Rudolph who died in 1864.

The basic deformity in the typical Habsburg skull is, according to Dr. Galippe, a lateral compression with corresponding expansion in the antero-posterior direction causing or at least associated with, exophthalmos. He does not mind matters in discussing the royal and noble families of Europe, nearly all of which were tainted with Burgundian blood, and, according to him, few of them

¹ *L'Hérédité des Stigmata de Dégénérescence et les Familles Succédant*. Par le Dr. V. Galippe, membre de l'Académie de Médecine. Paris: Masson et Cie. 1905.

of moral worth, and many of them of feeble intelligence; but after making full allowance for prejudice we must admit on the evidence that the Habsburg lip seems to be a dominant peculiarity, which crops up again and again, even among remote collaterals.

Dr Galippe shows also that a similar deformity existed independently in a marked form among the Medicis of Tuscany, although the deformity in this great mercantile family was not derived from any of the sources of the Habsburgs, it was enhanced by intermarriage with that family. It is most obvious in the portrait of Cosmo III by Westelient, and is unmistakable in that of the first Grand Duke Francis, and in many other members of that family.

Dr Rubbrecht of Bruges has studied this question from a slightly different point of view—that of the connoisseur of paintings and sculpture—and he published the results of his research in a beautifully illustrated work in which he discusses all the available portraits and images of the early members of the reigning families of France, Burgundy, and Austria, and especially the collection of portraits which formed the exhibition of the Golden Fleece at Bruges in 1907, to which pictures were sent on loan from various galleries, including the Royal collection of Windsor Castle, whence came a very notable portrait of the Emperor Charles V by a Flemish master. This portrait, for the faithfulness of which there is strong corroborative evidence, shows the deformity in its most acute degree. The brother of Charles, Ferdinand I, had also a very full and typical lower lip. When it is remembered that the Emperor Charles married his first cousin, and that his daughter and her son did the like, and that such consanguineous marriages were frequent in the family, it is easy to understand the persistence of the Habsburg lip.

From his iconographical studies Dr Rubbrecht comes to the conclusion that the Habsburg family inherits inferior prognathism from the royal houses of Spain and Austria, but that the large lower lip existed in the families of Burgundy and Spain before their union with that of Austria, and, further, that the lateral flattening of the skull, the long nose, and prominent eyes may be found in the ancestors of the Habsburgs in the houses of Burgundy, Spain, and Austria.

To the student of heredity both these books are of great interest. It is easy to understand the persistence of a hereditary trait, in a race which bred in-and-in for so many generations, but it is less easy to explain the persistent fecundity of the race under such conditions.

ANTRAL SEPSIS AS A CAUSE OF ILLNESS

A PERSONAL EXPERIENCE

A WELL-KNOWN surgeon, now retired from practice, sends us the following account of a prolonged period of ill health from which he suffered, attributable, in his opinion, to suppuration in the maxillary antrum. His age is now 73.

In the cold winter of 1916-17 when on duty in France he had severe toothache in the left upper canine, an abscess breaking through the upper margin of the alveolus. Immediately and for long afterwards boils occurred in various places and in 1920 a sebaceous cyst on the back suppurated in that year he began to have recurrent attacks of severe lumbago. In 1925 a sharp attack of influenza was accompanied by acute neuralgia which seemed to arise from the frontal sinuses and was followed by purulent nasal catarrh. During treatment with a mixed streptococcal and catarrhal vaccine a small patch of weeping eczema appeared on the outside of the left leg and gradually spread over an area the size of the palm. It was intensely irritating and at times was almost bullous. After each dose of the vaccine there was definite reaction in the eczematous area. The general condition was that of mild toxæmia with a large excretion of free uric acid. In 1926 while the patient was still getting about with the troublesome eczema phlebitis developed in the left posterior tibial vein opposite the eczema and spread up the femoral to the junction of the superficial and deep femoral veins with great oedema of the thigh and leg. The vaccine was stopped and during nine weeks in bed the eczema practically cleared up though threatening recurrence at times.

L'origine du type familial de la Vaseon de Habsbourg Bruxelles G. Van Oert et Cie, 1910.

In January 1927, while sitting quietly the patient had severe pain in the cardiac region, spreading right and left, and accompanied by intense distress. He was obviously gravely ill. The face was ashen, and there was slight cyanosis but the pulse remained steady at about 70 and the heart sounds were clear. Amyl nitrite only gave slight relief and the pain and distress persisted for some hours. After a stiff dose of whisky in hot water the patient had a fairly good night. Next morning the temperature was raised, but the general condition seemed to have improved. It was found later however that the blood pressure, which a year previously had been 155/60 had fallen to 85/50 and a tentative diagnosis of ischaemic necrosis of the heart was made. Confirmation of this was afforded during the three weeks of desperate illness that followed for signs of transient local pericarditis appeared on three separate occasions and at times fibrillation was present. It was noticed that when the heart was irregular the patient had little or no pain, on the return of normal rhythm he suffered a good deal from a precordial ache and from more intense pain referred to the left shoulder which small doses of morphine relieved. For about ten days a blowing systolic murmur could be heard at the tricuspid area and the apex beat was displaced to the left. The blood pressure was persistently between 80 and 90 systolic and the general condition poor. The patient was extremely weak and flatulence further embarrassed his heart. Three weeks from the initial attack, when some improvement had begun, a pulmonary embolism occurred when he was at rest on his back. The moderate distress and anxiety soon passed off but the patch in the left lung gave rise to a good deal of intercostal pain some days later from pleurisy. In about three months the lung had cleared up, the apex beat was then in the nipple line in the fourth space and there was no murmur.

The pulmonary embolism was accompanied by a curious sensation something not absolute pain was felt in the left arm beginning at the shoulder and trickling down the arm to the left index finger the extreme tip of which became numb and has remained so ever since. The explanation seemed to be that a very minute cerebral embolus formed at the same time as the pulmonary infarct and the inference was drawn that the ischaemic necrosis affected either the walls of both ventricles or the intra-ventricular septum for clearly a lesion capable of distorting both the right and left circulatory systems must be postulated to account for the bilateral emboli. The degree of subsequent recovery suggested that the main lesion was in the septum rather than an extensive necrosis of the walls of both ventricles. An electro-cardiogram three months later showed unusual complexes in leads 1 and 2 and in both the T wave was upside down. Nine weeks after the anginal attack complete rest in bed was abandoned, and very gradually moderate activity was resumed. The blood pressure was then 120, and four months later it was possible without inconvenience to indulge in a little trout fishing and to play nine holes of golf.

The nasal catarrh continued and in July 1927 a specialist pronounced the left maxillary antrum to be very opaque. This was confirmed by radiography which showed the other sinuses to be healthy. Aspiration of the antrum drew off a quantity of horribly offensive pus, of which there had been no indication either by pain or by an offensive odour. An opening was made into the antrum through the inferior meatus and a tube retained for three weeks when the opening bled fair to be permanent. Irrigation was performed from time to time the bad odour disappeared and washing out revealed only a little pus. In November, 1927 a sharp attack of paroxysmal tachycardia lasted two or three hours. The pulse was over 150 and feeble breathing was quick and the mental state was one of anxiety. The attack ended suddenly and the pulse came down to about its normal beat of 60 to 64. Five days later in the middle of the night another attack occurred rather more severe and lasting three or four hours. The heart evidently dilated in these attacks the apex beat was well beyond the nipple line but under treatment by digitaline the pulse became slowed to 50 and the apex beat came back gradually to the nipple line. The tachycardia was thought to be due to auricular flutter the blood pressure then was barely 120. As the washings from the antrum continued to contain much flocculent pus the antrum was opened in December through the canine fossa under local anaesthesia. Two pieces of what appeared to be bone or tooth about half an inch long and nearly a quarter of an inch thick were found lying loose in the cavity and were removed. Another fragment was not removed as it seemed unnecessary to continue the operation. On January 1st 1928 the blood pressure having risen a good deal the canine opening and that in the inferior meatus were both enlarged under ether the remaining fragment of loose bone was removed the portion of the antral floor over the canine region which showed active inflammation was chiselled away and the antral cavity thoroughly cleansed. The antrum now appears free from infection and the mucous membrane under direct inspection by the naso-pharyngoscope looks healthy.

Commenting on this history, the surgeon patient concludes that in 1917 the antrum was infected from the

canine tooth. The infection became chronic, and led to re-infections of the nasal cavity with recurrent coryza. The attack of influenza in 1925 probably caused an acute re-infection of the antrum. Administration of a vaccine some months after influenza, in the presence of antral infection and pus, seems to have induced a toxæmia, which caused the eczema, with general disturbance of metabolism, and later the phlebitis. When the cardiac attack occurred in 1927, with a considerable rise in temperature, it was at first thought that influenza was responsible, but the general phenomena of influenza were absent, and it seemed likely that the suppuration in, and absorption from, the antrum was in fact responsible. Once the antrum was drained the patient's general condition improved greatly until the attacks of auricular flutter in November, 1927. Since then there have been no other similar attacks, attributable no doubt to the rest taken and to the radical treatment of the antrum. The patient's general health has greatly improved, the toxic look is gone, he has had no boils since the antrum was emptied, his colour is good, and his weight has increased from the normal. Moderate physical exercise can be taken without inconvenience, and a certain amount of public work is discharged. The heart is, of course, a damaged organ, but functions regularly except during attacks of flatulence. Colds in the head were frequent up to June, 1927, but none has been experienced since until October, 1928.

The nose and throat specialist thinks that the virulence of the infection led to a necrosis of a localized area of the maxilla below the anterior nagle of the antrum. Gradual separation occurred, and, following the line of least resistance, necrosed into the cavity of the antrum. Thus a loose body which microscopically proved to be decaying bone, was found in the cavity. Suppuration in the antrum of great virulence was the result. No pain was present, and, owing to the consequent loss of smell, the offensive odour was not detected by the patient.

The striking point about the case is that it was possible for a dormant lethal sepsis to remain undiscovered in the body for many years, and to give rise to distant toxic effects which more than once brought the patient to the verge of death.

LOCAL GOVERNMENT REFORM

MEDICAL ASPECTS OF PROPOSED CHANGES

THE main task before Parliament on its reassembly on November 6th will be the disposal of the Government's scheme for the reform of local government and of its financial relations with the local authorities. These changes follow upon the decision to embark upon the plan for the relief of productive industry, propounded by the Chancellor of the Exchequer in his last budget speech, by means of what is commonly described as the "de-rating" of agricultural, industrial, and transport properties. The details of these proposals are already common property, and legislation to give effect to the rating relief scheme has already been placed before Parliament.

It may be recalled that as a result of this measure the local authorities will suffer a considerable diminution in their existing revenue from rates, and that it is therefore proposed to compensate them by grants from the Exchequer. The Government has decided that the execution of its scheme demands, first, a change in the basis of its contributions to local services, and, secondly, a substantial measure of local government reform. In this connexion it has been decided that there is a clear case for reform in the Poor Law and in highways administration and the main primary effect of the proposed changes will be to transfer the responsibility for these services to the county and county borough councils.

Overlapping in Medical Services

A full account of the proposals is given in a memorandum¹ prepared by the Ministry of Health for the information, primarily, of the local authorities concerned in England and Wales. The subject, however, is of

peculiar interest to the members of the medical profession, and deserves their closest attention. It is clear that the carrying out of the scheme will have important effects on the public health service in practically all its branches, and in many areas it will be the prelude to complete reorganization. The memorandum expresses the view that the proposed transfer of the Poor Law administration to the counties and county boroughs is in the traditional line of development of English local government, and recalls that when the parish unit was found too small for its task the larger union was created to supersede it. Under present conditions, it is suggested, the union is often in the position formerly occupied by the parish, and the magnitude of Poor Law work demands that it should be undertaken by local government units of first importance. Further, every rural union in the country has institutions which, with the decline in their areas in the number of persons relieved institutionally, are seldom full, and as regards facilities for medical treatment cannot economically be brought up to date. The memorandum proceeds:

Meanwhile other authorities charged with the duty both of preventing disease and of treating the sick have been established with the result that their functions overlap those of the boards of guardians. The transfer of the Poor Law to county and county borough councils would eliminate this overlapping and would make possible a better classification of the sick and would lead to economies in the provision of institutional treatment, the general demand for which is everywhere steadily expanding.

Administrative Changes

It will be seen from this extract that something much more than a simple transfer of functions is to be expected from the proposed reform, and this is made even clearer by the outline given by the Ministry of the changes in the existing practice in Poor Law administration which will arise. Here, it may be pointed out, the Government evidently intends to allow considerable latitude to the authorities concerned in the manner in which they will discharge their new functions.

After the passing of the Reform Act and before it comes into operation on April 1st, 1930, each county and county borough council will be required to submit to the Ministry a scheme of its proposed arrangements for the execution of its new duties. The memorandum gives an indication of the provisions which may be included in such schemes. It will be permissible to delegate or refer any of the new functions (apart from rating or borrowing powers) to an existing or specially constituted committee of a council, or to a local subcommittee for a particular district. Such committees or subcommittees may contain a minority of co-opted persons, such as former members of Poor Law authorities and members of other local authorities. Where a county or county borough council decides to provide for co-option this must apply to women as well as to men.

Delegation of Poor Law Services

It is suggested that in delegating Poor Law functions to existing committees of a county or county borough council assistance to mothers and children under 5 years might, for example, be a matter for the maternity and child welfare committee of the council. Similarly the education of Poor Law children might be dealt with by its education committee, which might undertake the maintenance of children in institutions, although the cost of this service would not attract an education grant from the Exchequer. Where the council of a county district is a local education authority or a maternity and child welfare authority such services may be delegated to that body. The memorandum states that existing Poor Law Officers will be transferred to the new authorities and proper provision for compensation, where necessary, will be included in the bill. In London as a result of the projected reform, the Metropolitan Asylums Board and the Metropolitan Common Poor Law Fund will cease to exist, the London County Council will assume responsibility for the services now maintained by the Board.

Grants for Health Services

As part of the general scheme of reform the Government proposes to review various grants in aid at present made to local authorities and to widen the scope of the Exchequer grants to make up the deficiencies due to de-rating. Among the grants to be reviewed (that is, abolished) are the percentage grants in aid of certain health services—tuberculosis, maternity and child welfare, welfare of the blind, venereal diseases, and mental deficiency. In place of these percentage grants, and of the others associated with them in the memorandum, is to be substituted a new Exchequer annual grant in aid, fixed in total and for each authority for a period of five years, and revised every five years—what is described as a "block grant." The total sum to be allotted is meant to cover the losses caused by de-rating

¹ *Proposals for Reform in Local Government* Cmd 3134 London H.M. Stationery Office, or through any bookseller 1928 1s net.

and by the abolition of existing grants and is to be augmented by a sum of £5,000,000 of "new money" from the Exchequer for England and Wales. During the transitional period from the old to the new financial system grants will be based partly on the existing method and partly on the basis of the formula which has been devised to secure a more equitable distribution.

Basis for the Block Grant

This formula is designed to give a weighted population, which will be the *primo factor* in allotting the grants. In arriving at this weighted population the estimated actual population will be increased by the percentage by which, at the last previous census, the number of children under 5 years of age per 1,000 of the population exceeded 50, and by other factors designed to compensate for low rateable value, high unemployment, and low density of population. Ultimately the whole of the grant will be distributed under this formula.

Interference with existing arrangements under which certain borough and district councils administer the maternity and child welfare service for their areas is not contemplated, but certain financial adjustments will be necessary. Modifications in the financial provisions of the scheme will be required in its application to London.

SECOND REPORT OF THE ROYAL COMMISSION

The second report of the Royal Commission on Local Government, the preparation of which has been expedited on account of the proposed action of the Government in this sphere, was issued this week, and will be reviewed in an early issue. The report recommends a reorganization of areas to increase efficiency, after a general review of existing units. It is suggested that county councils, in consultation with county district councils, should be required to frame a scheme for the appointment of whole-time medical officers of health, and that where part-time posts fall vacant steps should be taken to secure the appointment of whole-time officers. The Commission considers that the school medical service should remain in the hands of the local education authorities, and that provision should be made for these authorities assuming responsibility for maternity and child welfare work, in certain circumstances, where this service is not already under their control. Modifications are also proposed in the existing system for the allocation of responsibility for supervision under the Midwives Acts and for the treatment of ophthalmia neonatorum, and in connexion with the provision of infectious disease hospitals.

SICK-ROOM ACCOMMODATION AT PUBLIC SCHOOLS

A RECENT memorandum¹ giving the results of an inquiry into the standards of "sick accommodation" at a large number of English public schools is likely to serve as a useful guide to those responsible for providing such accommodation. It is the work of Dr. W. Dalrymple Champneys, one of the medical officers of the Ministry of Health, and is issued by the Ministry.

The types of accommodation found may be classified into four groups: temporary sick rooms at each of the boarding houses, special buildings called sick houses for the reception of non-infectious cases, infirmaries accommodating all cases of sickness, surgical infectious non-infectious and out-patients, and sanatoriums in which infectious diseases and sometimes non-infectious diseases are nursed. The problem of calculating the proportion borne by sick accommodation to boy population at a given school was complicated by the fact that at schools where studies are used as bedrooms these may also be reckoned as sick rooms. In such schools, as each boy may have a room of his own and the special sick rooms must be added to this total, the number of house sick rooms may obviously be larger than the number of boys in a house. Moreover, some schools provide outside accommodation for surgical and infectious cases though it is impossible to allow for this fact in an inquiry concerning the accommodation provided by the schools themselves. An examination of the statistical tables provided in the report brings out the great differences that exist between the sick accommodation of various kinds provided at different schools. For example, the maximum accommodation of sick boys in houses expressed as a percentage of boy population is 10.7 (105.4 if studies which may be used as bedrooms are included); the minimum is 2.9. The maximum of beds in outside houses for infectious cases is 15.3; the minimum 4.5.

The average number of infectious beds outside the houses is about three and a half times that of non-infectious beds.

These figures are of value in showing that the minimum standards of accommodation suggested in a later part of the report are already exceeded in a number of schools, and these not the best endowed of those included in the scope of the survey. The standard laid down by the Voluntary Hospitals Commission in its memorandum on the construction of voluntary hospitals was used for gauging the adequacy of space per bed provided in the wards of a number of school sanatoriums. Only in one or two cases was this standard attained or exceeded, in the great majority nominal accommodation was not compatible with this standard. It is generally not practicable to provide sanatorium accommodation for the large number of cases of sickness which may occur during an extensive epidemic. There exists, therefore, a problem of extra bed accommodation, which at present is dealt with in various ways. At some schools two or three dormitories are taken over, or even a whole house, as an annexe to the sanatorium. At one school a dormitory of 50 beds adjoins the sick house, with which it communicates by a door, usually kept locked. At another school the medical officer has caused two large dormitories of one house to be specially modified so that they can be converted into wards at the shortest notice. Some of the large schools have an out-patient department, where sick boys attend for examination, the administration of medicine, or the treatment of minor surgical complaints. Some schools keep records of a complete examination carried out when the boy enters the school, and of his height and weight at the beginning and end of each term. One school provides for a thorough dental examination once a year, with the result that the amount of dental cases in this school has been reduced by 50 per cent. in the course of four years. An attempt was made to estimate the extent to which sick bed accommodation is used, with a view to determining a standard of sick bed provision. It was generally found that statistics were completely lacking, or were insufficient for the purpose of the inquiry. Dr. Champneys suggests that all medical officers of public schools might adopt a method of expressing sickness rates in the form of boy days, the number of boy days of sickness being obtained by multiplying the number of boys going sick by the average number of days absence per boy on account of sickness.

The second part of the report considers the principles that should guide schools in providing new sick accommodation or extending that which exists. The amount of such accommodation must be calculated in terms of the total resident boy population, probable developments of the school, the purposes for which the accommodation is required, and the type of organization prevailing at the school. The total number of sick beds, including those in all four groups of accommodation, should be not less than 18 per cent of the boy population. The provision of sick beds in the houses—a suggested minimum of beds being 6 per cent of the total boy population—is essential, except in schools so highly centralized that sick boys can be removed to the infirmary, sick house, or sanatorium in a closed conveyance at any hour of the day or night. Sick room beds should be arranged in two rooms to allow for accommodation of an infectious case pending its conveyance to the sanatorium. For schools in which each house has its own sick rooms the total number of beds outside houses should be not less than 12 per cent. Where the infirmary or sick house takes the place of such rooms for a part or the whole of the school a corresponding proportion of beds must be deducted from this figure. The number of non-infectious beds outside houses should be not less than 2.5 per cent of the total boy population, of infectious beds not less than 9.5 per cent. The choice of a site for an infirmary or a sanatorium will be governed by such considerations as area, accessibility, elevation, drainage, water supply and probable developments round the site. The accommodation for infectious and non-infectious cases respectively should be arranged either in different parts of the building as far as possible from each other, or be on different floors, the former alternative being preferable. The out-patient department should be situated in the portion reserved for non-infectious cases. The suggested minimum standards of space allotted for each bed—the most important consideration in planning wards of any type—are: wall space 8 ft, space between beds 5 ft 6 in, floor space 100 sq ft in large wards and 120 sq ft in small wards, and effective air space 1,000 cu ft in large wards and 1,200 cu ft in small wards.

¹ Ministry of Health. Memorandum on the Accommodation for the Sick Provided at Certain Public Schools for Boys in England. London: H.M. Stationery Office, 1928. 1c.

It is, however, strongly recommended that for infectious or respiratory diseases bed space should be considerably increased by spacing out the beds or leaving one unoccupied bed between every two patients. With regard to sanitary annexes, it is suggested that the ideal arrangement is for every ward to have its own well-ventilated annexe, separated from it by a ventilated lobby. Provision for the performance of emergency operations is strongly recommended. An adequately equipped ward or room in the non-infectious part of the infirmary may serve in the absence of a room specially constructed for this purpose. Similarly, facilities for x-ray examination are of value, especially for the detection of fractures, which are of common occurrence on the football field.

The report concludes with some general indications of the present position with regard to the construction of sick accommodation in hospitals and sanatoriums.

TREATMENT OF PULMONARY TUBERCULOSIS IN NEW ZEALAND

As the outcome of insistent demands for increased accommodation for patients suffering from pulmonary tuberculosis in New Zealand, Mr. Young, the Minister of Health, after consultation with the New Zealand Branch of the British Medical Association, appointed three medical men to act as a committee of inquiry. These were Dr F. Fitchett, professor of clinical medicine and therapeutics in the University of Otago (chairman), Dr D. Eardley Fenwick, and Dr T. W. J. Johnson. The report of this committee, which has now been presented to the House of Representatives, deals with the whole question of treatment and prevention of this disease in New Zealand, and more especially with the class of tuberculous patients admitted to the sanatoriums of the Dominion. To facilitate their inquiries the three members of the committee were officially appointed assistant inspectors of hospitals, and in this capacity they visited all the various centres, where a large number of witnesses were examined.

It would appear from this report that in New Zealand, as in other civilized countries, the incidence of pulmonary tuberculosis has declined steadily during the past sixty years. The fall has been uninterrupted, and does not seem to have been influenced by any of the remedial measures introduced in the last thirty years for the direct treatment of the disease.

Though pulmonary tuberculosis has been a notifiable disease since 1901, the earlier returns are stated to be unreliable owing to neglect on the part of some doctors, some being opposed to notification, the increase noted in 1925-26-27 over any previous years is attributable to more patients being notified. In this connexion we might add that in England the subject is also regarded by the public health authorities as being still somewhat unsatisfactory. In Sir George Newman's report for 1926 it was observed that a considerable proportion of tuberculous patients were not notified before death, and a larger proportion only during the last six months of life. More reliable information is given by the death rate figures. In the New Zealand report it is shown that the mortality rate per 10,000 of the population has fallen from 9.70 in 1872 to 3.88 in 1927. These figures place the Dominion in a favourable position. "Indeed," as the report complacently states, "in no other country in the world for which reliable statistics are available is the death rate so low."

The Health Department, which supplied statistical information, was found to be alert in initiating measures for combating pulmonary tuberculosis, and to have kept abreast of the progress in preventive medicine during recent years. These measures include (1) notification, (2) inspection of the homes of tuberculous patients and distribution of leaflets, (3) medical examination of school children, and care of the malnourished and of those who have been brought in contact with the disease in their homes, for whom there are open air schools, nutrition classes, and health camps, (4) the establishment of tuberculosis dispensaries, (5) the segregation of chronic cases in hospitals, (6) the treatment of other cases in sanatoriums, (7) research.

In each of the four chief cities of the Dominion a hospital is reserved for the accommodation of advanced cases of pulmonary tuberculosis, but throughout the country patients in all stages of the disease are to be found in the general hospitals and in annexes attached to them. The committee is of opinion that this class of hospital is not being used to the best advantage of tuberculous patients, because not only is no suitable accommodation specially reserved for them, but there is also a disinclination to admit such patients. It recommends that hospital boards should modify their policy and admit, preferably to specially arranged annexes, cases in all stages of the disease. It is pointed out that while in New Zealand the possibilities for home treatment are great, medical practitioners and students must be given the opportunity for studying the disease if such treatment is to be satisfactory. This cannot be secured if such patients are denied admission to the general hospitals.

The sanatoriums seem for the most part to be suitably situated and well designed, though in three instances it is noted that they have not advanced beyond the early shelter-aggregate plan. While the accommodation in these institutions is adequate, with the exception of Otaki District, it is evident that such is not the case with the hospitals for chronic patients. Provision for these is a step in prevention which is always better than cure. In New Zealand the advanced chronic case is not regarded as a suitable inmate for their sanatoriums. In the North Island the superintendents of the sanatoriums have practically no voice in the selection of patients, they do not see them before admission, and this work is largely in the hands of tuberculosis officers on the Wellington and Auckland Boards. In the South Island selection is made by the medical superintendent of each sanatorium.

As regards the question whether the action taken against pulmonary tuberculosis, other than the provision of institutional beds, is sufficient, the committee finds that the Department of Public Health and the local authorities throughout the Dominion are fully alive to all the means available for sanitary reform, and are active in making them effective. There appears to be a real need for convalescent homes for adult patients. The great fear the public has of infectivity of pulmonary tuberculosis apparently closes the already established general convalescent homes against the tuberculous subject.

The Health Department is recommended to deal sternly with medical practitioners who neglect or decline to notify cases. More domiciliary supervision is advocated in the form of the employment by local authorities of visiting nurses, and it is stated that in the committee's opinion the institutional treatment of chronic open cases should have the first call on funds available for prosecuting the fight against tuberculosis. Under the heading of research it is advised that more definite information should be obtained with regard to the treatment of tuberculosis among the Maoris, and that more active measures be taken for the control of the disease in Maori districts. It is regretted that comparatively little pathological research is being carried on in the Dominion. Sufficient co-ordination of all the agencies dealing with pulmonary tuberculosis is not being undertaken, though signs of progress are noted in some parts. Especially is this seen in the control of sanatoriums, some being governed by the Health Department and some by hospital boards.

In its final recommendations the committee suggests that a division of tuberculosis be established in the Health Department, and that a director of this division be appointed. Further, it is suggested that the routine use of tuberculin in sanatoriums be discouraged, and that the stay of minimal cases should not, as is now the case, be unduly prolonged. The medical superintendents of sanatoriums are urged to admit all cases that would be likely to benefit, and it is further recommended that the establishment of voluntary aid associations should be encouraged.

While pulmonary tuberculosis is not regarded as a grave menace to New Zealand, this highly useful and well drawn-up report should be a most helpful contribution, in view of the stimulus it gives to the authorities for the better co-ordination of the measures and of the efforts now employed in fighting the disease. It appears from a general survey

which is included that New Zealand stands high compared with other countries in the favourable conditions it offers to tuberculous subjects. There is no stint of good food, the climate is good and has a wide range, the financial resources of individuals are greater than those of persons in the same social grade in other countries, and the standard of medical education is high. It cannot be denied that good food, fresh sunlight, and freedom from worry still remain the three leading factors in the proper treatment of tuberculosis.

India.

Overcrowding in Mental Hospitals in India

REFERENCES to the need for increased accommodation and improved arrangements for the treatment of patients in mental hospitals occur in several reports from various provinces on the working of these institutions in 1927. Major-General F. H. G. Hutchinson, surgeon-general to the Government of Madras, in his report on the mental hospitals of the Presidency, states that the accommodation at the Madras Hospital has been found insufficient, and that extensions are also urgently required at Calicut, adding that some progress can be recorded in the modernization of the existing buildings. Certain alterations and additions have been made or sanctioned, but more extensive developments are regarded as necessary. In a note accompanying the annual statements of the Nimgui Mental Hospital, in the Central Provinces, the inspector-general of civil hospitals, Colonel J. Norman Walker, remarks that the outstanding feature of the year was the insistent demand for accommodation, which could not be met. Overcrowding was mitigated to some extent by keeping some sick patients in the hospital ward and permitting a few to sleep in the verandahs at night, while the admission of non-dangerous male patients was restricted. Colonel Walker calls attention to the association of chronic focal sepsis with mental disorders of the type most frequently met with, and states that he is submitting proposals for the establishment of a dental department and the engagement of a throat specialist to treat such cases; thus, he believes, should make it possible to reduce considerably the average stay in hospital and reduce congestion. The report of the Punjab Mental Hospital, Lahore, also records that serious overcrowding was experienced. In Assam, according to the report of Colonel G. Hutchinson, inspector-general of civil hospitals, there was overcrowding in the provincial mental hospital at Tezpur. The reconstruction scheme, however, has progressed very satisfactorily, and provision has been made for ample accommodation on modern lines. When the work is completed in about two years' time quarters will be provided for 690 inmates, against 441 at present. This will solve the difficulties in connexion with overcrowding and the segregation of new admissions and special diseases.

Cholera Control at the Hardwar Kumbh Fair

Elaborate arrangements for the prevention and control of epidemics and the provision of sanitary measures were necessary in the months of February, March, and April last year through the occurrence of the Kumbh fairs, held every twelve years, at Brindaban and Hardwar, in the northern part of the United Provinces. It is estimated that the total attendance during the five days of the Brindaban fair was 2,900,000, and the total at the Hardwar fair 8,000,000. These fairs are attended by people from all parts of India, including several districts where cholera is endemic, and a stringent system of inspection was therefore instituted over persons entering and leaving the area by road or rail. A detailed account of the measures adopted in connexion with the Hardwar fair is given by Lieut.-Colonel C. I. Dunn, I.M.S., director of public health for the United Provinces, in an appendix to his annual report. It may be recalled that Sir Leonard Rogers last year took considerable interest in this matter, and a note on the efficiency of the prophylactic measures appeared in the *Journal* of December 31st, 1927 (p. 1242). Lieut.-Colonel Dunn states that the area was divided into eight circles, each constituted as a complete unit

under the charge of a medical officer of health, with a staff of medical assistants, sanitary inspectors, vaccinators, disinfecting gangs, and other auxiliaries, each circle having hospitals both for general and infectious diseases. Extensive provision was made for sanitation and for increasing water supplies. Every camp and lodging-house was visited and an endeavour was made to see each occupant daily, other means being also employed to ensure the detection of disease. These measures were very effective in reducing the incidence of, and mortality from, cholera, while the establishment of the system of inspection of pilgrims from other parts of India minimized the effects of this immense movement of population in spreading the disease. In 1915—the year of the last Kumbh fair—the number of deaths from cholera in the United Provinces after the dispersal of the fair was 89,993, the corresponding figure for 1927 was 28,285. Lieut.-Colonel Dunn refers to the danger caused by the presence of persons who are incubating cholera, and of carriers, who may easily escape detection, and suggests that the only hope of preventing the introduction of cholera into Hardwar by such cases would be either the quarantining of all pilgrims entering the fair from infected areas or their inoculation against cholera. In connexion with the Hardwar fair, about thirty private hospitals and dispensaries were maintained by voluntary agencies between 40 and 50 medical officers, and over 2,100 other members of the public health services, reinforced by 350 police on sanitary duty, were employed, while several hundred men of the railways were also placed on special duty during the fair. The opportunity was taken to promote educational work through the distribution of leaflets, the delivery of lantern lectures, and the provision of cinematograph displays. It is interesting to note that in view of the importance of this type of propaganda a change has been made in the United Provinces in the health organization to release an assistant director of public health for whole-time duty in charge of the provincial hygiene publicity bureau, over 14,500 lectures were given by public health personnel in 1927.

Reconstruction of the Government General Hospital, Madras

The report of the Government General Hospital, Madras, for 1927 contains a detailed account of the scheme for the reconstruction of the hospital on which work has been commenced. It is claimed that its completion will provide for Madras a general hospital which will bear comparison with any in the East. The accommodation will be increased from 540 to 650 beds, thus relieving the congestion which is being experienced in certain departments at present. Several minor improvements have already been effected in the existing buildings, which date from 1772, and further changes will be made under the remodelling scheme. This scheme provides for the demolition of a number of sheds around the main building and the erection of new structures to accommodate surgical wards, an operation block, an out-patient department, a casualty ward, a venereal block, pathological laboratories, an x-ray institute, and administrative accommodation. All the new and existing buildings will be linked together by corridors at various floor levels where necessary, and special facilities will be provided for the clinical instruction of students from the medical school attached to the hospital. New offices are also being provided in the scheme, which will, it is expected, take four or five years to complete, at a cost, excluding the pathology block, of about £295,000. The clinical teaching of students has been entirely reorganized during the year, and is now conducted on the lines followed in British medical schools.

New Hospital at Peshawar

It is expected that the new hospital now under construction at Peshawar to serve the civil Indian and European population of the North-West Frontier Province will be completed by the beginning of next year. The hospital occupies a site of about ten acres, and will provide 154 beds, including a European ward of twelve beds. It owes its existence to the initiative of Colonel C. I. Bierley, chief medical officer of the province, who, in 1925, formulated a scheme for the provision of a modern provincial civil hospital, the need for which had been felt in the

mon. The foundation stone was laid by Lady Reading in 1926. A contribution of about Rs 1,69,000 has been made by the Government of India, and a sum of Rs 3,10,000 has been provided by the Peshawar Municipality, while public subscriptions have amounted to Rs 1,60,000. Considerable additions to those sums, however, will be required to cover the cost of work still to be done.

Scotland.

Scottish Board of Health

THE draft of the Reorganization of Offices (Scotland) Act, 1928, which has now been issued, provides for certain departments being organized under the Secretary of State for Scotland, and several boards, including the Board of Health will now be converted into departments, it is proposed that the change should take place at the end of the present year. The Secretary of State for Scotland has designated as the head of the Department of Health for Scotland Mr. John Jeffrey, C.B.E., who will be permanent secretary to the department. Mr. Jeffrey was appointed to the clerical staff of the Board of Supervision in 1892, and on the abolition of that board was transferred to its successor, the Local Government Board for Scotland. He served as secretary of the Committee on Poor Law Medical Relief in 1902, as secretary of the Royal Commission on the Poor Laws and Relief of Distress, and later as general superintendent of the poor under the Public Health Act for the Northern Highland district. When the National Health Insurance Act came into force in 1911 he was appointed secretary to the Scottish Insurance Commissioners, and in 1919, on these Commissioners being amalgamated with the Local Government Board to form the Scottish Board of Health, he was appointed general secretary of the new board.

Glasgow Royal Infirmary

A new wing, completing the reconstruction scheme of the Glasgow Royal Infirmary, was on October 12th opened by Sir John Gilmour, Secretary of State for Scotland. Lord Provost Sir David Mason presided over a large assembly, and said that they were met to put the final seal on a great undertaking—the reconstruction of a great infirmary. During the years which had been occupied in alteration not a single patient had suffered inconvenience. Mr. James Macfarlane, chairman of the board of the Infirmary, outlined the work of reconstruction, which he said had been initiated by Sir David Richmond in 1897. The actual building was commenced in 1905, and the work of rebuilding the main hospital had been finished in 1914, when the complete building was reoccupied, and was opened by the King. The lost portion of the reconstruction scheme had been delayed by the outbreak of the war, but was now concluded. The Infirmary had been reconstructed by the voluntary contributions of all classes in Glasgow and the surrounding district, although there had been numerous outstanding benefactors who were commemorated by parts of the Infirmary being named after them. The building to be opened contained two casualty wards which were dedicated to the memory of John Ross of Lochbrae, Bearsden, and the lecture theatre, built on the site of the ward in which Lord Lister worked from 1861 to 1869, would bear a panel inscribed to his memory. Thus, after thirty-one years, the reconstruction of the Infirmary was now ended. Sir John Gilmour said that it gave him great pleasure to take part in a ceremony which meant so much for Glasgow and the wider field of surgical work, saying that he was one of those who were wholeheartedly in favour of retaining the voluntary principle in regard to hospitals. Glasgow Royal Infirmary had a noble history of development, but it should not be entirely on the generosity of those whom he heard described as "merchant princes" of the city that this great institution should depend for its support. Such a hospital was the concern of every man and woman in the city, and if this was recognized by all a state of financial stability would be achieved which was essential for the future. The speaker

then referred to a new development which he suggested was necessary. In the Royal Infirmary they were retaining in hospital for a period of cure and for the healing of wounds numbers of patients who might be removed to another area, perhaps to some annexe. It would be the height of folly to proceed with such a scheme until a way could be clearly seen to meet the heavy expenditure and daily cost, but he would suggest to those responsible for directing the affairs of the Infirmary that the provision of an annexe in the outskirts of the city should be their next ambition. He looked forward to the co-ordination of general services in the great cities and in the country, and to the removal of some of the services which, in his opinion, as they were worked to-day, were less effective than they might be. There must be, however, behind such changes the genuine interest of every citizen in voluntary hospitals, which had been the great incentive of their work in the past. He then declared the reconstructed building open.

Edinburgh Chair of Chemistry

Professor James P. Kendall, who has been appointed professor of chemistry in the University of Edinburgh in succession to Sir James Wolke, delivered his inaugural address on October 9th. Principal Sir J. Alfred Ewing presided. Professor Kendall, who had spent fifteen years in America, took for his subject "Chemistry in America," and reviewed the growth of this subject in the United States from its beginnings in the eighteenth century, pointing out that in its early days the subject had been influenced to a great extent in America by the teachers of Edinburgh University. In his own department at Washington Square College of New York University there were in 1919 40 undergraduates and 3 members of the staff, while in 1923 there were 1,200 undergraduates and 14 teachers, and in 1927 2,500 undergraduates and 60 teachers. Many American universities had found it necessary to regard chemistry not as a single subject, but as one of several branches, so that in many places chemistry had become a faculty in itself. One naturally asked where all these thousands of chemists in America obtained employment. Some went into teaching, some into research institutions under the Government or other bodies, but most of them went into industry. The necessity for having trained chemists—as distinct from routine chemists—in various industries had been recognized in America earlier than in this country. In America for at least a decade trained chemists had been employed in industry, and various industries had initiated research laboratories for purely academic work in the belief that this might lead to results valuable to themselves. Still, the demand for chemists was greater than the supply, and chemical industries had to pay young chemists salaries as high as those given in the universities. Industry was in some cases depleting the universities of their teachers, but this problem was beginning to be solved by the scientific staffs of the large industrial laboratories helping the universities in the education of the students. In this way, too, the industries fixed their attention on the more promising students whom they expected to secure in the future.

Veterinary Science in the West of Scotland

A public meeting was held in Glasgow on October 19th under the chairmanship of the Lord Provost, Sir David Mason, to appeal for funds to secure the continuance and improvement of the Glasgow Veterinary College. Professor Glaister said that the governors of the college were appealing to the citizens to prevent the extinction of a college which had done good work for the past sixty-eight years. From 1809 until 1926 the Royal (Dick) Veterinary College had received from the Government sums for capital and for maintenance amounting to over £71,000, while during the same period the Glasgow college had received amounts totalling only some £16,000. He did not agree with the view now held by the Government that one veterinary college should suffice for the whole of Scotland. The Duke of Montrose, honorary president of the college, said that the Government had suggested to agriculturists that they should ignore the cultivation of cereals and take up animal

husbandry, if they did this they must have behind them an up-to-date veterinary service. In the Glasgow district there were something like three million head of cattle, and it was necessary to exercise care in preserving these and keeping away scourges. He thought, therefore, it was essential that they should maintain an up-to-date veterinary college in the locality. Sir Robert Wilson, chairman of the Glasgow Education Authority, moved a resolution recommending the appeal of the governors to public bodies and citizens in Glasgow and the West of Scotland, as well as to stock raisers and owners. He was informed that the education authority had power to assist an institution such as the college, and he considered it would be a public scandal if the college had to shut its doors for want of support. It was pointed out that £20,000 would be required, and it was suggested that 100 persons might be found willing to give £200 each for the purpose.

Ireland.

Rockefeller Fellowships in Dublin University

WITHIN the last few months the trustees of the Rockefeller Foundation have given their assent to a scheme for the establishment of research and teaching fellowships in connexion with the medical school of Dublin University and three fellowships each worth £500 a year have been provided. One came into being on October 1st, another will be created in October, 1929, and a third two years later. The fellowships are residential and each holder will be required to work in a department of Trinity College Medical School, mainly on research but with some teaching as part of his duties. The present scheme is tentative in character, and will be subject to review after five years. Under this scheme Dr R. A. Q. O'Meara, M.Sc., has been nominated as Rockefeller Foundation Fellow in Public Health, his appointment dating from October 1st.

Voluntary Patients in Mental Hospitals

In connexion with the death recently of an ex-soldier, who was run over by a railway train in Dublin, Dr J. O'Connell Donelan, medical superintendent of the Grange-gorman Mental Hospital, in the course of a report, states that the press account of the inquest proceedings conveyed the impression that an application for the man's admission to Grange-gorman Mental Hospital had been refused. This was entirely erroneous, for no application had been made. The doctor who attended the man had stated that he had written a letter recommending his admission as a voluntary patient. Apparently this letter was delivered but did not reach Dr Donelan personally. In any case he could not have done more than issue a blank form of application, with a set of instructions for its completion. To secure the admission of the deceased, the statement points out, the application would have had to be completed by the patient's wife, father, or other relative, the medical certificate of insanity by the patient's doctor, and the recommendation for admission signed by a peace commissioner. It appears that the patient's father received an application form, but took no further action. Dr Donelan was, of course, debarred from admitting anyone until the legal formalities had been complied with. Dr Donelan's report admits that these regulations may seem "red tape" in the eyes of the coroner concerned but points out that neither the committee nor the medical superintendent is responsible for them. At the adjourned inquest on August 29th the wife and father of deceased said that they had never observed any signs of insanity in him and his medical attendant stated definitely that at no time could he have certified him to be insane. On this evidence the patient was not eligible for admission to a public mental hospital, and the medical superintendent would have been powerless to take any action in his case. Nevertheless, the coroner's jury returned a verdict of suicide while insane. The question of the admission of voluntary patients to public mental hospitals has been under consideration in the Free State for a long time but nothing has yet been done to alter the law. Voluntary patients can however be admitted to private institutions on complying with certain formalities,

one of which is an application to the inspector of mental hospitals in the patient's own handwriting. Had the coroner been aware of the law, it is suggested, the misunderstanding and unpleasantness which arose at the inquest, and which was reported so prominently in the press, could not have occurred. The committee of the hospital expressed its approval of Dr Donelan's action.

County Hospital Surgeon and Fees for Private Cases

At a recent meeting of the Tyrone County Hospital Committee the chairman read a letter from Dr Bradley, secretary of the Tyrone Division of the British Medical Association, in which the Division protested against the committee of management of the hospital imposing, as a condition of the appointment of a surgeon, a provision that he should forfeit all fees for operations. As an alternative the letter suggested that a certain number of beds should be reserved as private beds for the hospital surgeon, where he could charge fees for operations. They also suggested that a number of beds be allocated for difficult midwifery cases, that a maternity nurse be appointed, and also that a dental clinic be established in the hospital. The chairman said it was distinctly understood that the salary fixed covered all emoluments. Eventually it was decided to state that the committee would be prepared to confer with the Division on the points raised.

Health Insurance Medical Certification in the Free State

At a recent meeting of the executive committee of the approved societies a statement, supplied by the National Health Commission, was read in connexion with the working of the district medical referee scheme. The medical referees are appointed by the National Health Commission, and are independent of the approved societies. It appears from the statement that 13,395 applications for a second medical opinion were received in 1927, and that of those 409 (3 per cent) were rejected as unsuitably selected for examination, and 581 (4.3 per cent) were not proceeded with owing to the issue of final certificates prior to the date fixed for examination, leaving 12,405 references in regard to which notices to attend for examination by the district medical referee were issued by the Insurance Commission. An analysis of the result of these notices throws an interesting light on the system of medical certification under the Act. No fewer than 4,410 claimants (35.6 per cent) failed to attend, some (presumably a very small number) supplying certificates of physical inability to attend, some declaring "off" after receipt of the notice and before the date fixed for examination, and some simply ignoring the summons and therefore becoming disentitled to the benefit claimed. The remaining 7,995 claimants were submitted to medical examination, in 3,200 cases the referees concluded that the claimants were not incapable of work within the meaning of the Insurance Act, while only 4,795—representing 60 per cent of those examined, but only 38.6 per cent of those summoned—were, in the opinion of the referees, incapable of work and entitled to further benefit. Considering the above statement, and the particulars supplied by the National Health Commission to the Irish Medical Committee, there is no doubt that an extraordinary disproportion exists in the number of certificates issued by medical certifiers under almost exactly similar conditions, including the incidence of illness. An example of the conditions obtaining under the existing method of certification was given in the *Journal* of March 3rd, at page 374, together with an account of the estimated effects of the proposed adoption of the county area as the basis for the payment of medical certification capitation fees. Practitioners who are certifiers for sickness benefits under the National Health Insurance Acts in the counties of Cavan, Cork, Kilkenny, Limerick, Tipperary (S.R.), Wexford, and Wicklow have now declared against the decision of the National Health Commission to change the area of the pool for payment of certification from the dispensary district to the county, and have expressed their desire to adhere to the agreement they entered into in 1915 with the Commission, which assumed the dispensary district as the area of the pool for rural districts and urban areas with a population of less than 10,000. The main objection to the change of the area is that most medical certifiers would have the capitation fee for medical certifi-

entation of insured persons reduced from 2s 8d or 2s 3d to as low as 9d. This reduction would, however, mean a very substantial increase in the capitation fees of those doctors whom the National Health Commission and the approved societies choise with issuing an abnormally high number of certificates. In view of this the decision of the Commission to change the area of the pool is regarded as inexplicable, particularly as it has always been agreed between the Commission and the Irish Medical Committee that a medical certifier should not be encouraged to issue certificates involving an increase in the agreed capitation fee. So far no count, with the exception of Clare, has signified its willingness to accept the county pool, and it appears that Clare has done so in the absence of figures to show the undesirable effect of the change.

England and Wales.

Medical Service in Liverpool Cathedral

THE Liverpool annual medical service was held in the Cathedral on Sunday, October 14th. It was attended by a large number of medical men and women, of whom sixty were in robes and formed a procession. The sermon was preached by the Bishop of Liverpool, who dwelt on the importance of joining the spiritual and psychological with the medical in the processes of healing, in accordance with Christ's double command to preach and to heal. He also spoke of the wrong attitude which some people had towards disease and pain. He considered that it was not God's will that people should suffer. The Lessons were read by Dr Murray Cairns and Dr Bernard Chavasse. The Lord Mayor (Miss Margaret Bervan) attended in stato, and a large congregation was present. The collection, £97 4s 6d, was in aid of the Royal Medical Benevolent Fund.

King Edward's Hospital Fund for London

The statistical report for 1927 on the finance of London hospitals, prepared by the hospital economy committee of King Edward's Hospital Fund, follows the lines of the previous issue, which was the first of a new series, but includes particulars relating to two more hospitals, bringing up to 136 the number covered by this survey. Where figures for earlier years are given, however, they are generally in respect of all the hospitals now included, and therefore differ from the figures previously published. An interesting general review is given of the hospitals as a whole, with numerous coloured graphs illustrating the changes in the volume of work and in finance during the past year, while detailed analyses are furnished of the income and expenditure of each institution. There has been a steady increase in the number of beds available and beds occupied since 1923, the number of beds available increased by 420 during 1927, making the total 15,040 against 13,640 in 1923. The average number of beds occupied was 12,430 last year, compared with 12,150 in 1926 and 10,960 in 1923. New in-patients numbered 212,000 and new out-patients 1,670,000, as compared with 175,100 and 1,514,000 respectively five years ago. During the past two years the rate of increase in beds available has exceeded the rate of increase in beds occupied, while the number of in-patients has risen appreciably each year the average period of residence has been reduced. In the out-patient departments, however, there has been an increase in the average number of attendances recently through the provision of such forms of treatment as light and massage, which are of protracted duration. On the financial side the report shows that the hospitals in 1927 more than made up the ground lost in the previous year in respect of income. The total general fund income amounted to £3,241,000, against £3,041,000 in 1926 and £2,958,000 in 1923. Donations increased by £61,000, receipts from patients by £66,000, and legacies by £76,000. It is interesting to note that receipts for services rendered have increased much more rapidly than income from any other source. Payments from patients, for example, have

risen from £562,000 in 1923 to £778,000 in 1927. The expenditure of the hospitals last year was £3,170,000, compared with £3,079,000 in the previous year, and £2,712,000 in 1923. There was therefore a net aggregate surplus for the year of £71,000, in 1926 there was a deficit on the aggregate, but in the three preceding years the surpluses shown were much greater than that of last year. These figures, however, merely represent a comparison between income and expenditure in the general fund, and take no account of accumulated surpluses or deficits of previous years or of appropriations from the general fund to expenditure on buildings and equipment. On this basis, 80 hospitals last year showed surpluses amounting to a total of £178,000, and 56 showed deficits amounting to £107,000, six of the twelve general hospitals with medical schools showed deficits, some of which were considerable, but the "group" deficit was very small. In addition to general fund income the hospitals received in 1927 £188,000 for endowment, and £896,000 for buildings and equipment. The statistical tables embodied in the report give particulars of the work done and the cost of working at each hospital, and are designed, by grouping institutions in classes, to enable management bodies to compare their expenditure with that of similar hospitals, and so to assist them in securing an economic administration. For the same purpose an appendix to the report gives the average consumption of selected commodities at different classes of hospitals. The hope is expressed that the report will be of assistance to managers in the performance of their duties.

King's College, London, Centenary Appeal

The occurrence next year of the centenary of the foundation of King's College, London, is being made the occasion for the issue of an appeal for £350,000, required for extension of the buildings and the provision of educational endowments. The college has acquired a 200 years' lease of nearly 5,000 square feet above the Aldwych station, and plans are being prepared for the erection of a new building on this site. The rebuilding of the existing south-east block will provide the urgently necessary expansion of the department of chemistry, which serves the three faculties of medicine, science, and engineering. New and better rooms for the department of anatomy, which now occupies the lower part of this block, will be constructed on the roof of the college, in immediate contiguity with the department of physiology. In the space thus vacated by the anatomical department new rooms will be made available for the use of the department of chemistry, increasing it by nearly 50 per cent, and permitting the development of teaching in accordance with modern requirements for the application of scientific research to industry. The estimated cost of this rebuilding is £125,000, and for the completion of the existing theological hostel £15,000 is desired. A further sum of £125,000 is urgently needed for the endowment of special chairs for the faculties of natural and medical science, arts, and engineering. Scholarships and bursaries will absorb a further £50,000, and a sum of £35,000 is required for the educational endowment of the department of theology. It is recalled in the appeal that the proposal to found the college was first made at a meeting in June, 1828, under the chairmanship of the Duke of Wellington. A Royal Charter of Incorporation was received in August, 1829, and King George IV, as patron, granted the present site in the Strand. Medicine was one of the first faculties instituted, and in 1839 King's College Hospital was established in Lincoln's Inn Fields. It is recalled that some fifty years ago King's College invited Lister to come to London in face of strong opposition from King's College Hospital. Before the war the full-time day students numbered 700, whereas at present there are more than 1,200 undergraduates, 300 post-graduates, and 500 evening department students. Another important development since 1913 has been the annual provision of free public lectures on the latest discoveries in science and art, these have attracted large audiences. An influential appeal committee has been appointed. Copies of a detailed statement of the more urgent needs of this institution may be obtained from the secretary, King's College, Strand, W.C. 2.

Correspondence.

X-RAY DIAGNOSIS

Sir,—I think Mr Paterson might have something to say if I, as a mere radiologist, had the courage or temerity to write on the fallacy of surgery in abdominal diagnosis!

As it is very clearly put in the excellent leader in the *British Medical Journal* of October 6th (p 617), almost all fallacies enunciated and discussed at the Cardiff meeting might be more correctly described as mistakes. And mistakes will always be made in all diagnoses—clinical, surgical, or otherwise. They are inevitable, experience alone will reduce their number.

Most of the so-called "fallacies" cited by Mr Paterson are well-recognized pitfalls to the inexperienced radiologist; they are mistakes which might even jeopardize a candidate's chance of passing the radiological diploma examination. Everyone will agree that nothing should supplant a careful clinical examination, many are equally convinced that there does exist the possibility of a radiological diagnosis. Dr Herniman-Johnson's contribution makes it clear that Mr Paterson's troubles would be lessened if he had the services of an experienced radiologist. A radiological investigation of the intestinal tract is essentially fluoroscopic, owing to the type of structure examined, radiographs being used to demonstrate conditions already diagnosed on the screen. The production of a satisfactory radiograph is, of course, essential, but does not necessarily imply correct interpretation or accuracy in diagnosis, and thus, after all, is the crux of the examination. Radiology, as well as medicine, is an art, it has many pitfalls for the unwary. The examination of the intestinal tract fairly bristles with them, and here errors in diagnosis may lead to serious results. There is a tendency nowadays for medical men to be jacks of all trades and masters of none. Many general practitioners consider surgery easy and perform all operations themselves, while others do their own pathology or radiology; unfortunately, the patient is often the victim of these "all-round" men.

Modern medical science is complex, no single brain can possibly cope with the complexities and intricacies of its innumerable developments. Some years ago I was reprimanded by a medical practitioner for daring to include a report with radiographs—being classified, no doubt, as a "medical photographer". One proudly hoped that this attitude had more or less passed away—I am, etc.,

London, W 1, Oct 15th

S GILBERT SCOTT

Sir,—Reading over Mr Herbert Paterson's paper, entitled "Fallacy of x rays in abdominal diagnosis" (October 6th, p 595), I find myself entirely at a loss to discover the fallacy in most of the examples given. They are, indeed, not fallacies, but gross mistakes and illustrations of lack of judgement.

Discussing the question of the use of x rays in cases of fracture, Mr Paterson condemns house-surgeons for sending cases for radiological report before making a diagnosis. He contends that a diagnosis should be made first. Why? The medico-legal aspect alone demands an x-ray examination in all such cases. Who may be certain that there is a fracture, we can never be certain that there is not a fracture. I was taught as a student to use my eyes and ears first and foremost, and my hands last, and the use of the eyes has certainly not been exhausted until x rays have been resorted to. Personally, if I had a suspected fracture, no surgeon should lay hands on me until I had had an x-ray examination made. After all, the patient is the first consideration, not the diagnostician. The statement that radiography must not be made a substitute for a thorough and careful clinical examination is repeated nowadays *ad nauseam*, and seems to me utterly meaningless. In more cases than not a clinical examination is only rendered thorough when combined with an x-ray examination.

Mr Paterson appears to be unduly impressed with the radiogram. The radiological report, more often than not, is based on a careful screen examination, and not on the radiogram, and if there is one thing a radiologist should not do it is to draw inferences by guessing. In the case of intestinal stasis a shadow cast by the remnants of a barium meal adhering to the mucosa should deceive no one, since it causes merely a ghost-like shadow. Moreover, if faeces can be examined for the presence of charcoal, they can be equally well examined for the presence of barium. To quote a case of local muscular spasm in the stomach being discovered at operation to be due to a diseased appendix, and not to a gastric lesion, merely shows that the radiological examination was not a thorough or complete one—that is, other possible causes for the spasm had not been investigated. The first illustration shown is a radiogram of the stomach, suggesting gastric carcinoma. I can see no resemblance in it at all to the appearance of a typical radiogram in a case of cancer of the stomach, and, even if there were any doubt, no diagnosis should be made unless the appearance is definite and identical on several examinations. The statement that duodenal ulcers are not often shown by radiography is, in my opinion, absolutely untrue. If a screen examination is carefully carried out most duodenal ulcers reveal evidence of their presence, although it may be more difficult to demonstrate them in a radiogram. Over 98 per cent of gastric ulcers will be revealed by means of a barium meal examination, and I do not agree that it depends mainly on their size whether they can be demonstrated or not. It is not a fallacy when a gastric or duodenal ulcer is missed by reason of the fact that the patient has not been examined in more than one position. This is merely another instance of incomplete examination.

Fig 2, again, is shown as an example of a radiogram, the appearance of which is said to simulate that caused by cancer of the stomach by reason of the fact that the stomach was incompletely filled with barium. I see no resemblance in it at all to a typical radiogram of gastric cancer, and if the stomach was incompletely filled with barium the examination itself is obviously incomplete. In the case of scybalous masses causing shadows indistinguishable from gall stones this is very easily cleared up by a repeat examination after purgation, and certainly would not mislead a radiologist of experience. To diagnose a doubtful shadow in the region of the ureter wrong as a ureteral calculus is another example of incomplete examination, since this can be cleared up by means of a uroteric catheter, etc. and if it is thought necessary to exclude the possibility of a stone having been passed into the bladder between the time of examination and operation, it is surely a simple matter to make a rapid screen examination immediately before operation.

Fig 4 is shown as an example of a shadow resembling the appendix in a case where the appendix had been removed. To my mind there is no resemblance at all to the shadow cast by a barium-filled appendix, and in any case the presence of the operation wound would naturally cause one to inquire if the appendix had already been removed.

Mr Paterson quotes a case where the radiogram of the stomach, in a case of advanced gastric cancer, showed no abnormality. This radiogram is unfortunately not shown, and is the one which I should have particularly liked to have seen. Personally, I find it extremely difficult to believe that a case of such advanced growth should fail to show some evidence in an x-ray examination. A radiologist is not called upon to diagnose adhesions merely because certain portions of the bowel are immovable, his report should simply be a statement of facts. If frequent observations are made it is not possible to mistake a dilated rectum or pelvic caecum for a distended ileum. This is not a fallacy, but bad observation. Lastly, in the case of healing gastric ulcers, it is not uncommon to find amelioration of symptoms coinciding with definite diminution in the size of an ulcer niche, and I find it difficult to believe that this is anything but good evidence of progressive healing—I am, etc.,

HOVE OCT 16th.

C GUY WHORLOW

RADIUM IN THE TREATMENT OF CARCINOMA CERVICIS

SIR,—In reply to Mr Malcolm Donaldson's letter (October 13th, p 675), I consider his remarks not only ungenerous, but absolutely unjustifiable, especially when he refers to my paper, read at the Cardiff meeting (October 6th, p 609), as liable to do a great deal of harm to the progress of the treatment of carcinoma of the cervix.

Everyone is not so fortunate as Mr Donaldson in having a large supply of radium available for the treatment of his hospital patients.

It is to say the least, regrettable that anyone having such advantages should publicly decry a colleague whose aims and objects are precisely the same as his own, but who has only a hospital supply of 50 mg of radium element at his disposal, and extremely restricted facilities for using even this small amount on the very large number of patients who are in urgent need of it.

The cases referred to in my paper as having 100 mg radium element were several private cases for whom the larger dosage (hired) was available. Originally I treated them by direct application as described in my paper, with astonishingly good results, but latterly I have employed a technique similar to that described by Dr Gray Ward, whose paper preceded mine at the Cardiff meeting—I am, etc.,

E FARQUHAR MURRAY, M.D., F.R.C.S.

Newcastle-on-Tyne Oct 15th.

HYPERPHORIA

SIR,—In your issue of October 13th (p 659) your reviewer of a book on extra-ocular muscles censures the recommendation of the author to use as much as 10 prism dioptres in prescribing prisms for this condition.

I think it right to point out that at least in certain cases such strong prisms, or even stronger, are of the greatest relief. I can cite the example of a man aged 30, a member of the medical profession, who has worn prisms for hyperphoria since 1917—at that time of total strength of 4 prism dioptres. In 1925 I found hyperphoria of 16 prism dioptres and obtained fusion with the use of 11 dioptres. I prescribed 5 prism dioptres apex up in the right eye and 4 prism dioptres apex down in the left, with complete relief of headache and diplopia. The patient's letter after trying these glasses states, "Having given the glasses four days' trial, I am delighted to say I have not found them so comfortable for years." In August, 1926, examination revealed 15 prism dioptres of hyperphoria. In June, 1927, complaint of recent discomfort was made. Hyperphoria was found to be 16 prism dioptres, and the prescription of a total of 10 prism dioptres was found to be comfortable. I feel sure that there is a certain amount of colour at the margin of objects owing to the use of such high prisms, but there is no question as to the relief afforded by the prisms.

Occasionally prisms relieve the discomfort of ocular palsy. A patient with a partial right superior oblique palsy after using as much as 8 prism dioptres in each eye for a whole year writes as follows: "What an inestimable boon the glasses are. No more double vision or headache."—I am, etc.,

London, W 1, Oct 16th.

HUMPHREY NEAME

BACTERIAL FLORA OF THE INTESTINE

SIR,—Professor Cruickshank's address (September 28th, p 555) raises a number of points of interest, both to clinicians and bacteriologists. It is my experience that some individual clinicians, friends of my own, have on occasion been inclined to assume an amount of knowledge on my part greatly in excess of what I am personally conscious of. While this is flattering in a way, it does not help much to a solution of difficult problems. I suggest to these gentlemen that if they will "read, learn, and unwardly digest" Professor Cruickshank's paper, their perspective will in future be better adjusted to the realities of the situation.

What one feels, in attempting practical work in connexion with the intestinal flora is the want of a normal

standard, and that everyone is therefore a law unto himself. This obviously leads to chaos—where we have now arrived. I have been examining films from faeces from time to time for twenty years, and I must confess that I am no more competent to decide when a film is normal or when it is abnormal than I was to begin with. One can judge that there is a predominance of Gram positive or of Gram-negative organisms as a result of experience, but that is about all.

At present, as Professor Cruickshank points out, "the examination of one stool may require many days' work." This is, of course, impracticable for most men in ordinary practice, even if such an examination were to yield results of therapeutic as well as academic interest.

Some time ago I had a patient who for a number of years was completely or partially incapacitated owing to an infection of the respiratory tract. I had myself treated him with a vaccine prepared in the ordinary way with little if any success. He went abroad and had similar treatment by another bacteriologist, also without much success. On his return home, acting on a suggestion originally, I think, made by Sir Almroth Wright, I selected from a comparatively mixed flora those microbes in the sputum which grew out freely in the patient's own blood, used as the culture medium for the preparation of a fresh vaccine. The success of this method was in this case quite dramatic.

I read, therefore, with unusual interest Dr Cronin Lowe's paper (July 21st, p 98), in which he deals with what has been termed "pathogen selective cultures." It seems to me possible that a useful working standard of pathogenicity for the intestinal flora might be evolved on the lines suggested in his paper, or on somewhat similar lines. I have been able to confirm Dr Lowe's observation that a patient's blood may inhibit growth from a certain quantum of his own faeces. In what proportion of blood to faecal matter will growth be inhibited in average healthy individuals? If this question could be answered it seems to me we should be within sight of a practical working standard for faecal investigations which would at all events enable us to substitute reasonable presumption for guesswork.

There is one point on which Professor Cruickshank is not, I think, perfectly clear—the impermeability of the intestinal mucosa to bacteria and their toxins. If he means that this impermeability is absolute I agree with Dr Jenkins in thinking that no proof of this has been adduced. If, on the other hand, he means that there is comparative impermeability to bacteria and their toxins in health, I think that everyone, both on theoretical and experimental grounds, would agree. The borderland, however, between health and obvious disease is, I think, wide enough to permit us still to retain the hypothesis of intestinal infection and toxæmia without inconsistency.—I am, etc.,

Manchester Oct 15th

J STAVELY DICK

ISCHAEMIC CONTRACTURE

SIR,—Perusal of Sir Robert Jones's most interesting paper on ischaemic contracture (October 13th, p 639) shows that even he claims little personal experience of the value of operative treatment in the acute stage. Probably this is due to the fact that patients are brought to him only after the acute stage is passed. At any rate it encourages me to place on record the following instructive case. The fact that ischaemia threatened a lower limb and not an upper is of little moment.

A man aged 29 sustained a Pott's fracture while playing football on Saturday February 26th. He was taken to hospital and treated by the house-surgeon on duty. The fracture was not a bad one and beds were at a premium, so a plaster cast was applied from the toes to below the knee, and the patient was sent home. He spent two sleepless nights owing to pain was sent to hospital again two days later and was admitted. I saw him for the first time that evening. He was in considerable pain and the toes were very swollen, so I gave instructions for the plaster to be removed. On the Wednesday morning I was asked to see him again. There was much swelling of the foot and leg, the foot was almost black and sensation and motor power were entirely lost. The calf was tense and unyielding to the touch and the patient complained of a feeling of tightness in that region. He was immediately taken to the operating

theatre and an incision was made through the skin and deep fascia on the inner side of the leg extending from just above the ankle to just below the knee. The muscles at once bulged through the fascia and the wound gaped widely a little fatty blood oozed from the veins. The patient was returned to bed and the limb was placed on its outer side with the knee flexed the position originally advocated by Pott. Next day the limb was still swollen but it was warm and pink it was insensitive and immobile, but it was alive. Several blebs had appeared on the skin.

From this time there was slow but steady improvement. The wound took over two months to heal, and there was a little sloughing of the muscle in the centre of the incision where, presumably constriction first occurred. The swelling subsided gradually, and sensation returned in a manner identical with what one would expect after primary suture of a divided nerve. At the present time eight months after the accident, sensation to pricking is present in part of the foot there is good range of movement at the ankle and no contracture. Union of the fracture has been delayed, but callus is visible on x-ray examination. The swelling has entirely subsided.

The lessons to be learnt from this case are obvious. I wish to place it on record solely as evidence of the value of free incision through the deep fascia in cases of threatened ischaemia complicating fracture—I am, etc.,

C C HOLMAN

Northampton, Oct 15th.

THE DEFINITION OF DRUNKENNESS

SIR,—With reference to the letter of Dr Sidney Matthews (October 20th, p 726), whenever I give evidence in a case where a person is charged with being drunk in charge of a car I never use the word "drunk," but state that the defendant was so much under the influence of alcohol that he was incapable of driving a motor car. If I am cross-examined as to whether he is "drunk," I decline to discuss that expression, owing to the fact that it is used in various ways by different people, and I maintain the definition given above.

This matter was clearly put by Mr F Freke Palmer in a discussion at the Society for the Study of Inebriety held in January, 1925. He gave the following opinion:

"As the question now being discussed is vital both to the person charged and to the public whose lives and limbs are endangered and as the magistrates and judges differ in their opinions as to what constitutes drunkenness there ought to be a definition of drunkenness. I suggest that it might be 'A person so affected by intoxicating liquor as to be a danger to himself or a danger or nuisance to others'—I am, etc.,

Bullth Wells Oct 20th

W BLACK JONES, J P, M D

SIR,—This vexed question is once again before the profession in the pages of the *Journal*. My sympathy is with Dr Matthews but that will not change the law.

Sir James Purves-Stewart, addressing the members of the Society for the Study of Inebriety, is reported to have given the following definition:

A drunken person is one who has taken alcohol in sufficient quantity to poison his central nervous system producing in his ordinary processes of reaction to his surroundings a temporary disorder which causes him to be a nuisance or danger to himself or others.

In those cases of drunkenness which are so frequently before judge and jury to-day in connexion with motor cars, etc., this appears to be a sound definition. If the man's condition comes within the terms of this definition then a police surgeon to my mind, is justified in going into the witness box and declaring the man to be "drunk" but as to whether he is fit or not to drive a car does not concern him. We must always bear in mind that we must be guided by the law as it stands and not attempt to guide the law—I am, etc.,

Chichester Oct 21st

A M BINFORD

SIR,—Most people will agree with the chairman of quarter sessions in ruling that Dr Sidney Matthews's evidence was too ambiguous to be accepted as evidence. There is no legal definition of drunkenness, whatever definition there is is a medical one. Specific tests for drunkenness are fallacious and misleading, and should never be applied. Indeed King's Regulations for the Army

forbids any soldier arrested for this offence being put through any test. The difficulties of borderline cases are considerable. In the case in question Dr Matthews considered the man to have been under the influence of alcohol and unfit to drive a car or ride a motor bicycle in consequence. So that he might with absolute justifiability have certified him as "drunk."

Speaking generally, a state of drunkenness can only be judged by the loss of fitness for any duty, either of self care and control and intercourse with others, or for a trade or business task, or for a naval or military duty, or any self-imposed duty. If a man is found unfit for any of these, the unfitness being due to alcohol and not to injury or disease, nor drugs taken under medical advice the possible effect of which the recipient has not been warned against by his doctor, then the man is technically and legally drunk. It must not be forgotten that drugs are a legal cause of drunkenness. It entirely depends on the conditions under which they are taken whether the person is culpable or not. A person taking drugs, even under medical advice, which he knows or is warned may cause symptoms (loss of co-ordination and control) akin to alcoholic drunkenness, is unfit to drive a motor car, and is culpable if he tries to do so.

The driving of a motor car requires a high degree of co-ordination and judgement, and even a still higher degree of the same is needed to ride a motor bicycle with safety. An amount of alcohol which may have no particularly noticeable effect on a man's ordinary conduct may still be sufficient to upset his co-ordination for the above purposes. So that unless the fitness to drive is taken as the test of sobriety in this class of case many offenders, who are a danger to themselves and the public, will escape scot-free from the major and possibly well-deserved charge. If the doctor called in finds no evidence of disease, injury, alcohol, or drugs, then the delinquent can only be charged with driving to the public danger—I am, etc.,

S H FAIRRIE,

Sandgate Kent Oct 22nd

Lieutenant-Colonel R A M O (ret.)

SIR,—In my opinion a medical man called to examine a person accused of drunkenness should not try to find out whether the person is "police court drunk" or drunk in "the ordinary sense of the word," whatever these undefined and loose expressions may mean. The examiner must form his own definition of drunkenness, and determine whether the examinee is or is not in a condition which coincides with that definition. It is for the court to decide whether the condition as described constitutes "drunkenness."

I enclose a reprint of an article of mine on this subject, which appeared in No 4, vol 1, of the *Police Journal* published quarterly by Philip Allan and Co., price 5s a quarter. If Dr Matthews would care for a copy I should be pleased to send him one—I am, etc.,

Thurlestone, Oct 22nd.

GORDON WILSON

ANAESTHESIA FOR REMOVAL OF TONSILS AND ADENOIDS

SIR—As a result of the eloquent descriptions of methods, both of operation and of anaesthesia, which have recently occupied your correspondence columns, operators must now be filled with envy at the dexterous rapidity (or rapid dexterity) of their more able colleagues, and with scorn at the sluggishness of those unfortunates who spend ten or even twenty minutes in the painstaking performance of such a trivial procedure as the removal of tonsils and adenoids. Or, of course, vice versa. Anaesthetists, not to be outdone, must now be equipping themselves with special gags, complicated inhalers, weighted intrabuccal tubes, and large cylinders of nitrous oxide, oxygen, and carbon dioxide.

To this discussion I offer one small but (I dare to say) important contribution—namely, a reminder that, in this operation above all others, "the best anaesthetic is a good anaesthetist"—I am, etc.,

Aberdeen Oct 13th

H ROSS SOUPER

INTESTINAL AMOEBIASIS IN BRITAIN

Sm.—Dr Hugh Willoughby in his letter (September 29th p 586) states that he would be interested to hear of other cases of indigenous intestinal amoebiasis in this country. In the course of the last eight years we have seen four such cases, and another in a patient who had lived only in New Zealand before coming to this country. The most instructive case was perhaps the most recent.

A boy aged 16 who had never been out of England developed diarrhoea with the passage of blood in small quantities at infrequent intervals. A mildly inflamed appendix was removed but the symptoms remained unaltered. Three months later a diagnosis of ulcerative colitis was made on sigmoidoscopic examination the appearance being that of simple ulcerative colitis.

He was admitted to New Lodge Clinic two years after the commencement of his illness. The lower part of the bowel accessible to examination was not ulcerated but occult blood was constantly present in the stools. Infected tonsils were removed and with rest diet and local treatment to the colon by lavage his condition improved, the test for occult blood becoming negative.

For a recurrence of symptoms he was readmitted in May 1928. Small superficial ulcers were seen by the sigmoidoscope. The whole mucous membrane was very friable and bled on the slightest touch. Improvement again occurred with rest and local treatment. On both occasions the stools and swabs from the intestinal mucosa were examined frequently both culturally and microscopically but no marked departure from the usual picture obtained in diarrhoea was noted. Various pathologists had made previous examinations on many other occasions with similar findings.

After a third relapse a few weeks ago sigmoidoscopic examination immediately revealed the typical picture of uncomplicated amoebic dysentery. The lesions had the appearance of small boils as described by Dr A F Hurst situated on perfectly normal mucous membrane. The base of each was redder than the surrounding pink mucous membrane. The apex of the unbroken lesion was yellow. A few had ruptured at the yellow apex and were discharging.

Treatment with emetine was immediately started and after four injections the mucous membrane was almost normal. After a full course of twelve injections all abnormal signs had disappeared leaving a perfectly healthy mucous membrane. Swabs were taken from the broken lesions before treatment was started, and microscopic examination revealed the presence of encysted amoebae of the histolytica variety.

This case would seem to show that routine examination of the stools is useless as the sole test for dysentery carriers. A positive finding would, of course, be of value but the value of a negative result is very slight. It is essential in all cases to use the sigmoidoscope, to use it early, and to use it frequently. If the condition is uncomplicated the sigmoidoscope will always establish the diagnosis although it may be impossible, even with a typical picture, to demonstrate amoebae.

Three of the other cases seen were diagnosed entirely on the sigmoidoscopic appearance, after repeated examinations of the stools by different pathologists had failed to reveal any sign of amoebic dysentery. These cases responded at once in the same manner as that described above to the administration of emetine injections. Two of these patients had received prolonged and unsuccessful treatment for colitis before being examined by the sigmoidoscope—I am etc.,

Windor Forest Oct 16th.

JOHN F VENABLES, M D

A LONG MEDICAL PEDIGREE

Sm.—I noticed in the *Journal* for September 29th (p 583) the record of a medical family, stating that it would be interesting to learn if this could be approached by any other, so I venture to send some particulars of mine.

My grandfather on the maternal side was the last medical man to be medical registrar for Scotland, he was succeeded by J Robertson W S. When I qualified and went to register Mr Robertson gave me a copy of my medical pedigree which he had compiled including only Fellowships of the Edinburgh Colleges and not original qualifications. He told me that, taking both sides of the house into consideration, I had the longest pedigree in the Register. I append the names with the years of admission as F R C S and/or F R C P Ed.

The successive generations on the maternal side are (1) Alexander Inglis (1717) (2) his sons W Inglis (1743) and Andrew Inglis (1789), (3) the sons of Andrew Tom Inglis (1817) and Archibald Inglis (1825) (4) the son of Archibald Andrew Inglis II (1863). On the paternal side were Thomas Dickson (1873) and his son, F K Dickson (1831). My eldest brother, T G Dickson obtained the triple qualification about 1896, and I graduated M B, Ch B Ed in 1905.

The Inglis family have mostly been in practice in Edinburgh, except that the original Andrew was for a time in Paris, and the last Andrew, my uncle, was professor of midwifery at Aberdeen University. My grandfather Archibald Inglis was president of both Colleges and with my great uncle, Dr Graeme Weir, was one of the founders of the Edinburgh Sick Children's Hospital. My paternal grandmother was a daughter of John Thomson physician of Minto House who founded the Thomson Bursaries. Thomas Dickson was superintendent of the Cheadle Royal Asylum and afterwards founded Wye House Private Asylum. Buxton he was also one of the founders and a member of the original staff of the Devonshire Hospital, Buxton. At the Wye House Asylum he was succeeded, first, by my father, and then by my brother. I myself have been in general practice here for the last twenty years.

This is a long medical pedigree. I have no means of finding out when the earlier members of it originally qualified, as I have only the dates of their Fellowships.—I am, etc.,

Oxford Oct 7th

FRANCIS H DICKSON

Obituary

GEORGE HALKET, M D, F R F P S GLAS,

Consulting Physician Royal Samaritan Hospital Glasgow

WE regret to announce the death of Dr George Halket, one of the founders of the Royal Samaritan Hospital for Women, Glasgow, which occurred at his residence in that city on October 6th.

George Halket was a native of Glasgow and entered the University there shortly before its transfer to the present site at Gilmohrhill. He graduated M B, C M in 1873, and proceeded M D in 1882, being admitted to the Fellowship of the Royal Faculty of Physicians and Surgeons two years later. After graduating he spent some time on the Continent, continuing his medical studies at Vienna and Berlin, where he devoted his attention specially to obstetrical and gynaecological work, which became his chief interest in life. On his return to Glasgow he commenced general practice in the Anderston district, where he was a popular figure for many years. For a short period he was medical officer to the Barony parochial board but found the tenure of this office incompatible with the increasing demands of his private practice. His specialized interest in gynaecology led him to recognize the need for institutional treatment and along with three of his colleagues—Dr Stuart Nairne, Dr Park, and Dr Thomas McKee—he established a clinic for women in 1886. The premises secured for this purpose consisted of a small hall with an adjoining shop, and were equipped by these four men. Their work, as it grew, attracted considerable attention, and the support of the public was soon enlisted for the venture so that it was possible to secure improved facilities and ultimately to establish the institution now known as the Royal Samaritan Hospital. For about twenty-five years, until 1911, Dr Halket served the hospital as its physician, and until his death its affairs held a high place in his mind and heart.

Throughout his career he displayed a keen interest in the scientific side of medicine, he served a term as president of the Glasgow Obstetrical and Gynaecological Society nearly forty years ago, and was vice-president of the Glasgow Medico-Chirurgical Society in 1898-1900. Dr Halket was a prominent member of Clarendon Church for many years, and at the time of his death was the senior member of the Kirk session.

Dr JAMES STEVENSON, who died suddenly at Clydebank on October 3rd in his forty-fifth year, was the son of a medical practitioner of that town. He was educated at Glasgow High School and proceeded thence to the University in that city graduating M B, Ch B in 1906. Three years later, after holding a resident post at the Glasgow Maternity Hospital, he succeeded to his father's practice in Clydebank. He was also medical officer for the Clydebank district of Old Kilpatrick parish, and police surgeon to the burgh of Clydebank. Dr Stevenson, who was a member of the British Medical Association and the Glasgow Medico-Chirurgical Society, was held in high esteem by his many friends and patients.

The Services

INDIAN MEDICAL SERVICE

THE following amendment to Rule 10 of the Study Leave Rules for the Indian Medical Service, published with Army Department Notification No 890, dated July 9th, 1926, has been made by the Secretary of State for India in Council

After the penultimate paragraph of the said rule there shall be added

'Study allowance may be given at the discretion of the Government of India or a Local Government for any period up to fourteen days at one time during which the officer is prevented by sickness, duly certified by a medical practitioner, from pursuing the sanctioned course of study

DEATHS IN THE SERVICES

Colonel Robert James Geddes, C.B., D.S.O., Army Medical Service (retired), died at St Andrews on September 27th, aged 70. He was born in Glasgow on August 13th, 1858, and educated at the university in that city, where he graduated as M.B. and C.M. in 1882. He also subsequently took the D.P.H. of the Scottish Colleges in 1903. Entering the army as surgeon on February 2nd, 1884, he became lieutenant colonel after twenty years service, and colonel on February 5th, 1913, retiring on December 26th, 1917. He had a long record of war services: Burma campaigns, 1888-89, medal with two clasps, Chin Lushai campaign of 1889-90, clasp, Meknau expedition, 1898, South Africa, 1899-1902, operations in Cape Colony, the Orange River Colony, and Transvaal, relief of Kimberley, actions at Paardeberg and Dreifontein, mentioned in despatches in the *London Gazette* of September 10th, 1901. Queen's medal with four clasps, King's medal with two clasps, and D.S.O. In the war of 1914-18 he served as D.D.M.S. of the Second and Fourth Corps of the British Expeditionary Force in France, was mentioned in despatches in the *London Gazette* of February 17th and June 22nd, 1915, and received the C.B. on June 23rd, 1915. From 1917 till his retirement in December, 1919, he filled the post of inspector of medical services in Scotland.

Captain Robert John Bertram Buchanan, R.A.M.C. (ret.), died at Eastbourne on September 23rd, aged 48. He was born on September 3rd, 1880, and educated in the medical school of the Royal College of Surgeons, Ireland, where he took the diplomas of L.R.C.P. and S., with honours, in 1903, and the D.P.H., also with honours, in 1906. After filling the posts of surgical resident at Stevens's Hospital, Dublin, resident medical officer of Monkstown Hospital, Dublin, and house surgeon of St Peter's Hospital, London, he entered the R.A.M.C. as lieutenant on January 31st, 1905, became captain on July 31st, 1908, and was invalided out on March 25th, 1916.

Universities and Colleges.

UNIVERSITY OF EDINBURGH

A GRADUATION ceremony was held in the Upper Library Hall on October 20th when the following medical degrees and diplomas were conferred

M.B. B.Ch.—M. Caplan F. M. Melmod
D.P.H.—Lucia L. O. Black Elizabeth F. M. Clark Edith F. Oromb
Isabel R. Gordon Betty M. Kennedy Mary V. Littlejohn
I. McCracken B. C. Mackay Margaret M. D. Miller A. L. H. Rankin
L. N. Sutherland Violet B. Tulloch J. M. Watt.

UNIVERSITY OF GLASGOW

A GRADUATION ceremony was held on October 20th when the following medical degrees were conferred

M.D.—J. A. Kerr * R. A. Lennie * Olive M. Somerville J. W. Hamilton

The degrees of M.B., B.Ch. were conferred upon the successful candidates at the final examinations whose names were published in our issue of October 13th (p. 680).

The Junot Memorial Prize for the most distinguished graduate in medicine for 1928 has been gained by J. S. M. Robertson.

The West of Scotland R.A.M.C. Memorial Prize for the candidate with the highest aggregate marks in medicine surgery, and midwifery in the Final M.B., B.Ch. examination held during 1928 has been awarded to G. L. Montgomery.

* With commendation.

UNIVERSITY OF DUBLIN

SCHOOL OF PHYSIC TRINITY COLLEGE

THE following candidates have been approved at the examinations indicated

FINAL EXAMINATION (*Materia Medica and Therapeutics Medical Jurisprudence and Hygiene Pathology and Bacteriology*)—P. S. Dalbie J. M. Gibson A. Rose N. A. Munnar P. L. O'Neill
R. Howerman C. Bowerman A. Rakoff J. B. Scott (In completion)
D. G. McCauley E. F. S. Morrison C. Ryan
M.A.O.—A. A. Shafik.

* Passed on high marks.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At the meeting of the Royal College of Surgeons of Edinburgh held on October 17th Dr Alexander Miles was re-elected president for the ensuing year, Dr A. Logan Turner vice president, and Mr John William Struthers secretary and treasurer.

The following 27 successful candidates, out of 78 entered having passed the requisite examinations in July, were admitted Fellows

D. A. Abernethy J. Berasteln B. E. Buckingham E. G. Collins
R. O. Craig B. B. Cadgill E. J. G. Glass E. W. Hayward
H. T. Jonning A. H. Johns A. E. H. Kendall A. M. Knistilleke
G. H. Lee J. P. S. Les D. A. P. Macalister C. W. R. McCaldin
G. W. M. Paterson G. Punshon G. Purdy W. L. Thomas
T. H. Thorp V. G. H. Wallace F. B. Walsh L. P. Waters,
A. H. Winchester W. W. Woodhouse R. E. Inle

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

THE annual meeting of the Royal College of Physicians of Ireland was held on St Luke's Day (October 18th), when Dr W. A. Wilson was re-elected president and Dr J. A. Matson elected vice-president.

The following Fellows were elected censors of the College: Dr J. A. Matson, Dr Speucer Shelli, Dr R. H. Hicks, and Professor J. T. Wigham.

The following officers were re-elected: Representative on the General Medical Council: Sir John Moore, treasurer, Dr H. Howley, registrar, Dr T. P. C. Kirkpatrick, librarian, Mr Robert Phelps.

The representatives of the Committee of Management under the Conjoint Examination Scheme were re-elected as follows: Dr Walter G. Smith, Sir John Moore, and Dr T. P. C. Kirkpatrick.

The St Luke's Day dinner was held in the College Hall in the evening.

Medical News.

AT the autumn dinner of the University of London Medical Graduates' Society, to be held on Wednesday next, October 31st, at 7.30, at the Langham Hotel, Portland Place, W.1, Professor M. Hajek of Vienna will be the guest of the society. This opportunity will be taken to give members of the society the latest information about the Bloomsbury site for the University, and of telling them what is being done in regard to that matter. Tickets are 10s. 6d. each, and members intending to be present at the dinner should send their remittances to the honorary secretaries, 11, Chandos Street, W.1, not later than October 30th.

THE annual dinner of the British Institute of Radiology, incorporated with the Röntgen Society, will be held at the Trocadero Restaurant, Piccadilly, on Friday, November 16th, at 7.45 p.m., with the President, Dr G. W. O. Kaye, in the chair.

THE winter course of lectures at the Central London Throat, Nose, and Ear Hospital, Gray's Inn Road, W.C.1, commences on November 9th at 4 p.m., when Mr J. D. McLaggan will speak on otosclerosis. They will be continued on succeeding Fridays at the same hour with the exception of a break at Christmas. Medical practitioners are invited to attend the lectures without fee. An intensive course of post-graduate study will be held at the hospital from April 29th to May 18th, 1929.

THE Fellowship of Medicine and Post-Graduate Medical Association announce that on Monday, October 29th, Mr C. S. Lane Roberts will speak on abdominal pain in pregnancy at the Medical Society of London, 11 Chandos Street, Cavendish Square, at 5 p.m., on Tuesday, October 30th, Mr Lionel Colledge will give a clinical demonstration at 2 p.m. at the Hospital for Diseases of the Throat, Golden Square, and on the following day, Wednesday, at 4 p.m. Dr S. H. Dawkes will give a demonstration on diet and disease at the Wellcome Museum of Medical Science, 33, Gordon Street, W.C.1. There are no fees for attendance at the above. A practitioners' course in medicine, surgery, and the special departments will begin at the Hampstead General Hospital on Monday, October 29th, and continue for two weeks, from 4.30 to 6 p.m. daily. Courses will be held in medicine, surgery, and gynaecology, at the Royal Waterloo Hospital (November 12th to December 1st), in neurology, at the West End Hospital for Nervous Diseases (November 19th to December 15th), in ophthalmology, at the Royal Westminster Ophthalmic Hospital (November 12th to December 1st), in proctology, at St Mark's Hospital (November 12th to 17th), in urology, at St Peter's Hospital (November 19th to December 1st), and in venereal disease, at the London Lock Hospital (November 5th to December 1st). Syllabuses and other particulars may be obtained from the Secretary of the Fellowship, 1, Wimpole Street, W.1.

DR P J KELLY, Surgeon General, British Gambia, has been appointed a nominated member of the Legislative Council of British Gambia and a member of the Executive Council of the colony.

The fifth American Congress of the Child will be held next December at Havana, where all the countries of South America will be represented.

The report of the Medical and Sanitary Department of the Government of the Gold Coast for the year 1926-27 states that the great increase in yellow fever gave serious cause for anxiety, 86 cases with 26 deaths occurring, against 8 cases with 5 deaths in the previous year. The disease affected Africans to a much greater degree than before, and outbreaks occurred over a wide area. It is noted that a large proportion of deaths among so-called non-humans of the white race continue to occur in those who do not reside in segregation areas. A steady increase in the incidence of tuberculosis is recorded, and the opinion is expressed that the problem is undoubtedly one which is growing, especially in connexion with labour in the mining centres. Schemes for housing improvement and for the provision of a large sanatorium will demand consideration in the near future.

The September issue of the *Kenya and East African Medical Journal* contains a statement that the Legislative Council at Mombasa has empowered districts to levy rates for the provision and maintenance of hospitals and other medical services, and that Nairobi and Mombasa have become definitely responsible for public health activities within their boundaries. It is anticipated that at first the Government will contribute financially towards local necessities. It is also announced that it has been decided to proceed with the long delayed building of the Medical Research Library. To the same issue of this periodical Dr J A. Carmichael contributes an article on the use of bismuth in yaws and syphilis. There is also an account of the meeting in April of the Tanganyika Branch of the British Medical Association.

In a recent issue of the *Weekly Bulletin* of the Department of Health of the City of New York it is stated that an epidemic of septic sore throat broke out in Lee, Massachusetts, in July. Within two weeks there were nearly 600 cases, with thirty-six deaths in a population of about 4,000. The epidemic ended abruptly on the enforcement of a local order requiring pasteurization of milk, this followed the recovery of haemolytic streptococci from a cow and from a number of persons concerned with a dairy. Contact cases were very few.

The sixth volume of the *Guide to Current Official Statistics*, issued by the Permanent Consultative Committee on Official Statistics, follows the lines of previous issues. The work affords an admirable, and indeed an indispensable, index to the mass of statistical information contained in Government publications, and is in itself sufficient justification for the existence of the committee responsible for its compilation.

The annual dinner of the staff and past and present students of the Royal Dental Hospital of London was held at the Trocadero Restaurant on October 20th, with the Right Hon. Sir W. H. Goschen, chairman of the hospital, and Sir Holburt Vining as principal guests. In proposing the health of the students and the school, the chairman, Mr G. G. Camplin, recalled the life and work of William Harvey as a stimulus to a high professional ideal. Mr S. B. Newton mentioned the noticeable improvements in the school since his days there as a student. He hoped to see the advent of a postgraduate course, even a three-day refresher course once a year, with every part of the hospital open and clinical demonstrations proceeding, would be very useful to a large number of men. Mr H. W. F. Freeth, the Saunders prizeman, said that the students of to-day were not unmindful of the fact that the majority of the advantages which they enjoyed were the direct outcome of hard spade work in the past by their predecessors. The dean, Mr H. Stoble, said that the number of students this year—117, of whom nine were women—was not quite as great as last. The examination results, about 60 per cent of successes, had been very fair. One student now registered was preparing for the B.D.S. examination of the University of London. The hospital welcomed B.D.S. students, and no school could better prepare the student for that degree as well as for the L.D.S. Much thought had been devoted during the year to the equipment of the hospital and to familiarizing the students with the advances in dental surgery. Some modified courses in radiology and anaesthetics had already been held, and a course in orthodontics was now being instituted. Any real demand for periodical refresher courses would be met. A research laboratory had been opened, and the school had obtained the assistance in an advisory capacity of many first-rate men, including the new honorary pathologist, Dr I. H. Maclean. The health of the chairman was proposed by Mr G. O. Whitaker, who paid a tribute to Mr Camplin's work at the Manchester Dental Hospital and elsewhere.

WI. have received the programme for the centenary celebrations of the Faculty of Medicine in Cairo, and the International Congress of Tropical Medicine and Hygiene, which will be held from December 15th to 22nd. Thomas Cook and Son, Ltd., Berkeley Street, W. 1, are in charge of the excursions, which include visits to Upper Egypt, Palestine, and Syria. The secretary of the congress is Professor M. Khalil, the Congress Bureau, I, Sharia Mazloum Pasha, Cairo.

A COURSE in colonial pathology will be held at the medical clinic at Bologna at the end of November, and will include the clinical aspects and pathology of colonial diseases, colonial hygiene, protozoology, entomology, helminthology, bacteriology, and serology. Further information can be obtained from the Director, Ospedale S. Orsola, Bologna.

A BALNEOLOGICAL congress will be held in Berlin from January 25th to the 27th, this being the fiftieth year since the foundation of the German Balneological Society. Details may be obtained from the general secretary of the congress, Fraunhoferstrasse 16, Charlottenburg, Germany.

WOMEN in Turkey were not allowed to study medicine until 1922, and the first to complete the curriculum obtained their licence in 1927. A certain number of Turkish women had already obtained qualifications in other countries, so that at the present time there are over fifty women doctors in Turkey.

WITH the consent of the Greek Government an Italian scientific commission has gone to Greece to study dengue. Its members are Professor Gabbi, director of the Medical Clinic of Parma University, Professor P. Neri, director of the Institute of Hygiene of Bari University, and Professor P. Pontano, lecturer in clinical medicine at Rome.

THE epidemic of dengue in Greece is subsiding. According to official statistics there had been 631 deaths from the disease in Athens and 1,040 in the whole of Greece up to September 20th, or no less than 1 per mille of the populations of the towns affected.

THE issue of the *Dermatologische Wochenschrift* for September 29th has been dedicated to Professor A. Buschke of Berlin, who is well known for his work on thallium and blastomycosis, on the occasion of his sixtieth birthday.

FRANZ L. THEYSEN, the oldest woman practitioner in Germany, celebrated her ninetieth birthday on September 7th.

DR ERNST DELBANO, professor of dermatology at Hamburg, has been elected an honorary member of the Italian Society of Dermatology and Syphiligraphy.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **The Editor, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS as well as orders for copies of the *Journal*, should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are *W.C.1* 2561, 2562, 2563 and 2564 (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are EDITOR OF THE BRITISH MEDICAL JOURNAL *Aitology Westcent London*.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.) *Articulate Westcent London*.

MEDICAL SECRETARY *Medisera Westcent London*.

The address of the Irish Office of the British Medical Association is 18 South Frederick Street, Dublin (telegrams *Bacillus Dublin*, telephone 62550 Dublin), and of the Scottish Office 7 Drumshigh Gardens, Edinburgh (telegrams *Associale, Edinburgh*, telephone 24361 Edinburgh).

QUERIES AND ANSWERS.

ADMINISTRATION OF LIVER EXTRACT

"W" asks how long it is advisable to continue the administration of liver extract in a patient with pernicious anaemia. This man aged 49 is just recovering from his third attack. The haemoglobin percentage is now 65, and the red blood corpuscles number 4,400,000. He has been taking one capsule of the liver extract daily for about twelve weeks.

WATER SOFTENING

"S S S" would be glad to know of a simple and economical method of softening water, or preventing the formation of "fur" in a domestic hot water supply

ELECTRIC STERILIZERS

"J H D" writes I should be glad to know if anyone with experience can tell me of electrically worked sterilizers, suitable for a small hospital, that can be depended upon and are fool proof

TREATMENT OF CHRONIC URTICARIA

Dr E C MUDIE (Glasgow), referring to the request of "Inquirer" on October 20th (p. 732), writes A child, aged 2½, was brought to me with a history of "epots" covering his body completely (except the cheeks), they came out in crops at frequent intervals. The condition had lasted for two and a quarter years and was tending to become worse. After searching among the various articles of diet for a sensitizing agent and applying different external and internal remedies without success I put the child on thyroid extract which was gradually pushed to his fullest tolerance 5 grains daily. An improvement set in almost immediately the full dose was given, the crops gradually lessened in amount and frequency, and finally stopped. It is now more than eighteen months since the last dose of thyroid extract was given, but the condition has never returned and the boy is perfectly healthy, mentally and physically. I have since tried thyroid extract on milder cases of urticaria with excellent results, so that my conclusions are that this painful condition must have some connexion with endocrine deficiency.

ADOPTION

Dr G O HARTLEY (1, Hutton Hill Gravelly Hill, Birmingham) writes A childless relative of mine is very desirous of permanently adopting a healthy girl aged about 2 to 4 years. I should be greatly obliged if anyone knowing of such a child in need of a good home would communicate with me.

WANTED—A HOME

In response to the request published under this heading in last week's *Journal* (p. 732), replies have been received from seventeen medical men, and these have been forwarded to "F R C S."

INCOME TAX

Commencement of Partnership

"G W M" writes to say that prior to April 1927, he was an assistant to his father in private practice, and carried on a panel practice of his own, and then became a partner in his father's practice by a verbal agreement but still carried on his own panel practice. Income tax returns were made on that basis and subsequently the terms of the partnership were set out in a deed executed on July 4th 1928, which recited that the partnership shall be held to have commenced as from April 5th, 1927. The Inspector of taxes declines to recognize the existence of the partnership prior to July 4th, 1928.

* * Two points need emphasis. The first is that the statement in the deed as to the date from which the partnership is to be regarded as having commenced is binding on the parties to the deed, but not on third parties—for example, the Revenue Department. The second is that though it is usual for partners to enter into a deed, that relationship can be legally established by other means—for example by the intentions of the parties stated and accepted by holding out to the public (for example, by newspaper headings, accounts, public announcement, etc.), that a partnership does exist etc. We advise "G W M" to remind the Inspector that the deed was not essential to the creation of the partnership, and to point out to him each circumstance as will serve to show that that relationship existed from April 5th 1927, onwards, and that the deed merely corroborated his terms.

Replacement of Car Obsolescence Allowance

"R G L" bought an A car in 1926 for £340 and was allowed £88 for depreciation for the year 1927-28. In 1927 he sold that car for £141, buying an E car price £295. He has claimed as an expense of the year 1927 £340—(£88+£141=) £209 (that is £131) but the Inspector declines to make this allowance treating the matter as one of a further capital outlay of £295—£141=£154, and as increasing future depreciation allowances only.

* * In effect "R G L" takes the view that the A car became obsolete in 1927 and claims the obsolescence allowance, the Inspector apparently holds that obsolescence is not involved and that "R G L" will have to look to the increased depreciation allowances for future years to put him right in the long run. The only legal decision in point is that given nearly twelve months ago in the case of the South Metropolitan Gas Company v Dadd—"R G L" might refer to a reply to

C A R M in our issue of March 10th last. The matter is not beyond doubt, but there is some tactical disadvantage in a contention that a twelve months old car is "obsolete" and if our correspondent is likely to remain in practice for some years he may prefer to look to the long run rather than contest the matter further.

LETTERS, NOTES, ETC.

WORKS ON HAEMATOLOGY

Dr A PINFI (Cancer Hospital, Fulham Road, S.W.3) writes I have been asked to undertake the preparation of abstracts of British works on haematology for the new French periodical *Le Sang*. The work would be much facilitated if authors would be so kind as to send me reprints of their papers. Articles dealing with diseases of the blood, symptomatic blood changes, blood cells, leucocyte enzymes, and blood chemistry are included.

INTRAVENOUS INJECTION OF INDIGO CARMIN

Mr A T ROCHE (London, W.1) recalls that in a letter printed in the *British Medical Journal* of May 26th (p. 921), he maintained that the dilution of indigo-carmin for intravenous injections should be 0.4 per cent and not 4 per cent. He finds now that in the chapter on diseases of the kidney in Walton's new *Text Book of Surgical Diagnosis* (1928) the figure is given as 4 per cent in spite of the fact that indigo-carmin is soluble only up to 0.8 per cent.

A SIMPLE ASPIRATION APPARATUS

Mr D G DUFF F.R.C.S. Ed. (Dunbligh) writes An aspiration apparatus is notoriously liable to be found wanting when most needed. The resort to laboriously emptying a thoracic effusion with a 20 ccm syringe proved too tedious an affair to day so the hospital vacuum cleaner was pressed into service an improvised connexion being made with the barrel of a 9 in ward dressing syringe and the bottle from the theatre oxygen apparatus, this then enabled the aspiration to be conducted in comfort to the patient, the small bore of the aspirating needle preventing too rapid an exhaustion. The rubber connecting piece is not present in all vacuum cleaners, but it was found that the metal tube connecting piece of the vacuum apparatus fitted closely inside the wide end of the glass syringe barrel and gave equally good suction.

SEA SICKNESS.

"J C M" writes As an acute sufferer from motion sickness myself I find your commentators on this subject a little wide of the mark. My own disability in that direction was first discovered by my nurse when I was some 16 months old. When sitting on a swing with me on her lap and swaying gently to and fro she found that I was caused to vomit. Since those far off days I have done much travelling by most kinds of transport except aviation, and I have been three times round the world. Naturally I have tried most remedies and have acquired a nice discrimination in the amounts of nausea produced by the various kinds of joggling, swaying, and other motions to which one is subjected. For a short sea trip there is nothing to beat going on board with an empty stomach, choosing the cabin immediately behind the one exactly amidships, and lying prone on one's bunk in the position advocated by Burney Yeo. Neither heat nor cold nor emotions, smells, stuffiness, nor anything else matters a straw in my long experience of motion sickness. In my youthful days, however, I found chocolates particularly beneficial. One patient of my own a boy 12 months old puzzled me much by sudden attacks of vomiting, until I discovered that they were caused by an energetic sister rushing him in his perambulator up and down a pathway. I am acquainted with the scientific explanation of Burney Yeo's position, but should be grateful for information.

MEDICAL TREATMENT IN CHINA

Dr A H SKINNER (Hankow) writes In reply to Fleet Surgeon Home's query on August 4th (p. 228) as to Chinese custom in respect of contract medical practice, I have heard the same story, that a family doctor is paid a retainer which ceases during illness, I fear it is a fairy story, or at any rate it is nowhere known in the centre of China. Native physicians call when sent for, are paid, depart, and do not call again unless asked to do so. A well-to-do patient may change his doctor half a dozen times in a week, his friends give him no flowers but express their active sense of sympathy by heading their favorite medical man to see the patient and prescribe for him. Priests of various sorts are also in emergency, invited to attend—these are cash transactions—so that the invisible powers may not undo the effect of the visible medicines. A Chinese friend of mine attached to the local army finds that his salary is less likely to be overlooked if there has been some sickness among the higher staff officers, and he has attended with good result. Fatal illnesses would probably result in considerable delay in his monthly wage payment. Also in "quiet" times, when the general health of the force is good, his salary, like that of most officers, may fall much into arrears. Incidentally, foreign doctors in the treaty ports have most of their foreign patients on a system of contract attendance. Chinese prefer their own system paying for attendance as and when they need it but we have on our books four native families on contract—one of these for over thirty years—during which time, I need hardly say, they have not enjoyed entire freedom from illness.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges and of vacant resident and other appointments at hospitals, will be found at pages 44, 45, 48, 49, and 50 of our advertisement columns and advertisements as to partnerships, assistantships and locumtenencies at pages 46 and 47.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 183.

An Address

ON

RECENT ADVANCES IN THE TREATMENT OF GASTRIC DISEASES*

BY

ARTHUR F. HURST, M.A., M.D. Oxon., F.R.C.P.,
Physician to Guy's Hospital.

IN May of this year I came of age as a member of the staff at Guy's Hospital. When I recall our knowledge of disorders of the stomach twenty-one years ago and compare it with that of to-day, it is at once apparent that most recent advances in treatment are the result of advances in diagnosis. Radiology was in its infancy in 1907, and only the grossest anatomical and functional abnormalities of the stomach could be recognized with its aid. To-day I am unwilling to diagnose a gastric or duodenal ulcer without direct x-ray evidence of its presence, and I do not think that my colleague Dr. P. J. Briggs has failed during the last five years to discover some abnormality in the outline or movements of the stomach in any case of carcinoma. Test meals were rarely given in 1907, and the significance of the results obtained was little understood. The modern fractional test meal not only shows how much acid is secreted, but it gives an accurate measure of the motor efficiency of the stomach, and affords the only means of recognizing gastritis—a common disorder, formerly diagnosed on insufficient evidence and to-day diagnosed with insufficient confidence. The significance of the presence of occult blood in the stools was unknown twenty-one years ago, and it is only in the past seven years that Dr. J. H. Ryffel at Guy's Hospital, and Dr. J. F. Venables and Dr. T. W. Turner at New Lodge Clinic, have so improved the methods of testing for it that it now ranks with the x-rays in value as a means of recognizing the organic diseases of the stomach. It is almost always found with active ulcers, and its gradual disappearance is an excellent measure of the success of treatment, whilst its constant presence in every stool in every case of cancer is of the utmost importance in diagnosis.

During this same period surgery has taught us that duodenal ulcer is a common disease with characteristic symptoms instead of an undiagnosable rarity. It has taught us how frequently gastric symptoms are the reflex results of disease in the gall-bladder and appendix. Finally, and most important, it has shown us how often it fails to cure the diseases it has taught us to recognize, and how often it gives rise to new and artificial diseases formerly unknown. It has thus stimulated us so to improve our methods of medical treatment that we may look forward to the day when all the unsuccessful gastrojejunostomies have been undone, and the only gastric operation the surgeon is called upon to perform is gastrectomy for early carcinoma.

THE TREATMENT OF ULCER

In the past the medical treatment of ulcer was frequently unsuccessful because it was not founded upon an adequate knowledge of its pathogenesis and was consequently not sufficiently thorough, because it was rarely continued until healing was complete, and because it was not realized that when the ulcer had healed the ulcer diathesis remained, so that unless the essential exciting causes were eradicated and the accessory exciting causes were avoided a recurrence was very likely. I shall briefly consider the principles of treatment, the evidence of healing upon which the duration of treatment should depend, and the instruc-

tions which should be given to the patient so as to make it possible for him to lead an active life without running danger of developing a new ulcer.

A PRINCIPLES OF TREATMENT

1 *The Acid Factor*—The presence of free hydrochloric acid is required for the development of an ulcer. A diet must therefore be chosen which produces as little secretion of acid as possible, and atropine and olive oil should be given to inhibit the secretion of acid, and alkalis to neutralize the acid when it has been secreted both during the day and, what is almost invariably neglected, during the night. I shall presently refer to some recent work on the relative value of the different alkalis and the danger of alkalosis, and how the latter can be avoided. The diet must also be one which contains nothing to irritate the ulcerated mucous membrane chemically or mechanically, and it must be adequate in quantity and quality to maintain the patient's nutrition.

Diet

In nearly all the well-known systems of dieting patients with ulcer tables are given in which changes are made at definite intervals, until, at the end of a varying period, a full or almost full diet is allowed. Such systems are most illogical, as a small superficial ulcer calls for a very much shorter period of treatment than that required for a large penetrating ulcer. Moreover, it is not obvious why any change in the treatment should be made until the ulcer has healed. Such schemes as those associated with the names of Leube, Lenhart, and Sippy, in which the diet is changed daily or every few days for two, three, or four weeks, have thus no rational basis. If a certain diet is suitable for a certain day, it is absurd to assume that every ulcer, whatever its size or position, and whatever the general condition of the patient may be, will have improved in twenty-four hours to just the degree which justifies the addition of an egg or a *zweiback* to the diet.

When the diet has once been modified so as to suit the special requirements of the individual, no further change should be made until all the available evidence shows that the ulcer has completely healed. I doubt whether it is really necessary to have any intermediate diet before the patient changes from the strict diet to the almost full diet of the "post-ulcer regime," which he must keep to for the rest of his life. As, however, it is impossible to be quite certain that an ulcer has healed, I give a diet intermediate between the strict diet and the post-ulcer diet for the patient to take for a week or two whilst he is beginning to resume his usual activities.

In various papers published between 1829 and 1835 Cruveilhier recommended an exclusively milk diet for the treatment of gastric ulcer, and soon afterwards Brinton introduced it into England. Since their day milk has, and I think rightly, formed the foundation of nearly every plan of treatment. Pavlov showed thirty years ago that its fat inhibits the secretion of gastric juice, and that its protein combines with some of the free acid. Freezer, Gibson, and Matthews (1928) have now demonstrated that milk neutralizes approximately its own volume of 0.3 per cent hydrochloric acid*. If, therefore, 1,500 c.c. (2½ pints) could be administered in such a way as to coincide with the varying rates and periods of acid secretion, the milk would by itself be sufficient to keep the gastric contents neutral throughout the day, if not more than 1,500 c.c. of juice containing 0.3 per cent hydrochloric acid were secreted. P. M. F. Bishop, D. Ellis, Evan Jones, G. W. Rake, and B. T. Squires have investigated the effect of different diets and different alkalis in the actual treatment of ulcer patients under my care by removing fractions from their stomach every fifteen minutes for several consecutive hours. It has been found that purely carbohydrate feeds have none of the neutralizing action of milk, and that the latter acts more satisfactorily in small quantities given hourly than in larger doses given two-hourly or still larger every four hours. The administration of milk every hour leads to complete achlorhydria for a considerable part of the day but free acid appears from

* Given in opening a discussion in the Section of Therapeutics and Pharmacology of the Annual Meeting of the British Medical Association Cardiff 1928.

time to time a quarter of an hour before the next feed is due, especially in the afternoon and evening (Chart 1). It is then that the addition of alkalis is required in order to obtain continuous complete neutralization.

CHART 1—(a) Ordinary fractional test meal (10 oz. gruel) keeps gastric contents neutral for only a quarter of an hour. (b) Milky feeds of 10 oz. keep contents neutral for half to three-quarters of an hour (Evan Jones).

2 The Infective Factor—The essential exciting cause of gastric and duodenal ulcer is infection. It is therefore necessary to eradicate completely any infective foci which may be found. Pyorrhoæa alveolaris requires treatment not only by the dental surgeon but by the patient, whose personal attention to oral hygiene can often bring about the cure of mild forms of the condition. All dead teeth should be x-rayed, and any showing apical infection should be extracted. Areas of rarefying osteitis should be looked for even in edentulous patients, as a residual streptococcal infection may persist for many years after infected teeth have been extracted, as Eyre was the first to show, and as Spencer-Payne has demonstrated in many of my patients. Infected tonsils should be enucleated and the nasal sinuses examined for obvious or latent infection, which should be treated by appropriate measures.

3 Accessory Factors—Tobacco is a very important factor in the pathogenesis of ulcer, largely on account of the increased secretion of acid to which it gives rise, the patient, therefore, should not be allowed to smoke during the period of strict treatment. As fatigue and exposure to cold often play a part in the development of an ulcer, it is best for the treatment to be carried out in bed.

B DURATION OF TREATMENT

Strict treatment must be continued until the ulcer has completely healed. The spontaneous pain often disappears within twenty-four hours, and it rarely lasts for more than a week. Deep tenderness and rigidity may be found considerably longer, but generally disappear long before healing is complete. The stools should be examined twice a week for occult blood, until three consecutive ones have given a completely negative guaiac reaction and have shown no spectrum of haematoporphyrin. The more active inflammatory phase of ulceration may then be regarded as past, but the ulcer is not necessarily healed. In the rare cases in which occult blood remains constantly present, even in specimens obtained through a sigmoidoscope, so as to avoid possible contamination from piles, and in spite of the disappearance of all other symptoms and signs, early malignant degeneration should be suspected, and the necessity for exploratory operation requires consideration. An x-ray examination must be made every week until the crater has completely disappeared. This is a most valuable sign of healing in gastric ulcer, but it is often difficult to recognize the crater in the irregular outline of the bulb in duodenal ulcer, as some permanent deformity almost always persists after the ulcer has completely healed. Only when spontaneous pain, tenderness, and rigidity, occult blood in the stools, and direct radiological evidence of ulceration have all completely disappeared for a week should the strict treatment be discontinued, and then only if the total duration of treatment amounts at least to four weeks, as, from what is known of their pathology, it is difficult to believe that even the smallest chronic ulcer will heal soundly in much under a month. Large ulcers require six or eight weeks, and very large and chronic ones, which

have penetrated the pancreas or liver, may require as long as three months.

C AFTER-TREATMENT

Investigations on the ulcer diathesis carried out at Guy's Hospital and New Lodge Clinic, and in New York by Draper, together with our observations and those of Ryle and Huddy on the familial occurrence of ulcer, have clearly shown that the tendency to recurrence after medical treatment, and of the equal tendency to the development of new ulcers in the stomach, duodenum, or jejunum after surgical treatment, are primarily the result of constitutional peculiarities of the individual. If he returns to the conditions which were present before his ulcer developed, it is only to be expected that a new one will form. This can only be prevented if, in addition to the removal of all foci of infection during the strict treatment, he is given instructions as to his diet and habits, which he must obey for the rest of his life.

If food is properly masticated, by the time it is swallowed it should be so well broken up, softened, and diluted by the saliva that it can no longer exert any mechanical, chemical, or thermal injury on the healthy gastric mucous membrane. Nothing which cannot be reduced to a fluid condition by chewing must be eaten, no pips or skins of fruit, whether raw or cooked, or in jam, marmalade, or cake, and no raw vegetables, no pickles, and no cooked vegetables except in the form of purées, are allowed. Everything which does not lose its chemically irritating properties by dilution with saliva must also be prohibited, this prohibition includes all forms of alcohol, strong coffee and tea, unripe fruit, and the majority of drugs. Smoking must be confined to a limited number of cigarettes provided with a mouthpiece containing a plug of cotton-wool, because of the chemical irritation caused by swallowing small quantities of tobacco juice and the increased secretion of gastric juice which follows the inhalation of nicotine.

ALKALIS

Until recently it had always been thought that the equivalent dose of various alkalis could be calculated from their chemical formulae. As, however, the theoretical conclusions did not agree with clinical experience, I asked Professor C. S. Gibson of Guy's Hospital to investigate the question by modern physico-chemical methods. This he has now done, with Mr. C. R. E. Freezer and Mr. E. Matthews. Their results are of great interest and of much practical value. In their first series of experiments an excess of the "alkali" was added to a constant amount of 0.3 per cent hydrochloric acid, and the hydrogen ion concentrations (pH values) of the resulting solutions were determined. It was found that the "alkali" could be classified as follows:

(a) Magnesium oxide and peroxide and sodium bicarbonate produce an alkaline solution which reaches a maximum and constant degree of alkalinity within a minute. This is higher for magnesium oxide (pH 10.0) than for sodium bicarbonate (pH 8.0). Magnesium carbonate attains neutrality in less than a minute and then becomes alkaline, reaching a maximum (pH 8.5) in two minutes.

(b) Sodium and potassium citrates and tribasic calcium and magnesium phosphates attain neutrality (pH 7.0) within a minute, and calcium carbonate attains neutrality in two and a half minutes, but none of the solutions ever become alkaline.

(c) Bismuth oxycarbonate only reduces the acidity to pH 4.0, the solution never becoming neutral. The proprietary drugs "alecol" (aluminium silicate) and "neutralon" (aluminium hydroxide), which have been much used for the relief of so-called "acidity," have even less effect, the final pH being 2.4 and 3.7 respectively.

In a second series of experiments it was found that the calculated chemical equivalent dose of the alkali required to produce neutralization always failed to do so, owing to the reversed action of water with the salt formed by the combination of the acid with the alkali. Instead of neutrality (pH 7) being attained, most of the alkalis had very little effect, the greatest reduction in acidity being produced by sodium bicarbonate (pH 4.1), and the next by sodium and potassium citrates (pH 2.3).

In a third series of experiments the quantity of 0.3 per cent hydrochloric acid neutralized by 2 grams (30 grains) of the alkali was determined. It was found that, weight for weight, magnesium oxide is the most efficient alkali and that bismuth oxy-carbonate is the least. Calcium carbonate, sodium and potassium citrates, and tribasic calcium and magnesium phosphates have less than one-fifth the neutralizing power of the same weight of magnesium oxide, sodium bicarbonate having rather more than a quarter.

The investigations of Grohn with fractional test meals showed that sodium bicarbonate and magnesium oxide, after neutralizing the acid present in the stomach, stimulated the secretion of more acid than they are, in fact, the most powerful stimulants of gastric secretion known, with the exception of histamine. As Preizer, Gibson, and Matthews found that these alkalis produce an alkaline solution when given in excess, in contrast with most alkalis such as calcium carbonate, sodium and potassium citrate, and tribasic calcium and magnesium phosphates, which produce a neutral solution, it appears probable that it is the alkaline reaction of the gastric contents rather than any specific property of sodium bicarbonate or magnesium oxide which stimulates the secretion of acid. Consequently, if the latter are given in doses insufficient to produce complete neutralization, no secondary stimulation of secretion is likely to occur.

It does not seem to have been realized in the past what efficient alkalis sodium and potassium citrates are. When the former is added to milk in order to combine with its calcium and so prevent the rennin of the gastric juice from clotting it directly it is swallowed, it loses none of its neutralizing power. Freezer, Gibson and Matthews found that milk neutralizes an equal volume of 0.3 per cent hydrochloric acid, so that citrated milk contains the properties of two efficient alkalis—milk and sodium citrate—as well as being an unobnoxious and valuable food (Chart 2).

On the other hand, it is customary to regard bismuth oxy-carbonate as an alkali, although it is interesting to recall the fact that the first bismuth salt employed in the treatment of gastric disorders was the subnitrate which was never supposed to exert any neutralizing action on the gastric juice. As so many patients believe they gain relief from the use of bismuth salts—the oxychloride and subnitrate being apparently as effective as the oxy-carbonate—their physical rather than their chemical properties may perhaps endow them with some soothing action, the nature of which is quite unknown. It has been suggested that they form a protective coating to ulcers, but Briggs has shown by radiological observations that even half an ounce of bismuth oxy-carbonate taken in suspension on an empty stomach does not as a rule adhere to the surface of even a large ulcer crater.

Sodium bicarbonate gives immediate relief to the pain in most cases of ulcer. This is due in part to the almost instantaneous neutralization of the acid present, and in part to the effect of distension of the stomach with gas on the mechanism of the pyloric sphincter. It is, however, an undesirable alkali in the treatment of ulcer, in spite of its popularity with patients and many physicians because as I have already pointed out the neutralization of acid is followed by a great increase in secretion. Moreover the distension of the stomach with gas may be dangerous if an ulcer is near perforation, and its stimulating action on peristalsis is an additional disadvantage.

Magnesium oxide has nearly four times the neutralizing power of an equal weight of sodium bicarbonate and no carbon dioxide is evolved, so that no gaseous distension of the stomach is produced. It has a mild aperient action,

and produces a smaller secondary increase in secretion after the initial neutralization than sodium bicarbonate.

Calcium carbonate has two-thirds of the neutralizing power of sodium bicarbonate, but it does not give rise to any secondary hypersecretion. It has been suggested that the calcium chloride which it forms in the stomach may have some influence in increasing the coagulability of the blood, and it has therefore been recommended when haemorrhage has recently occurred, but there is no deficiency in the blood calcium in such cases, and calcium salts given by the mouth have no effect on the coagulability of the blood.

Tribasic phosphates of calcium and magnesium act, according to Greenwald (1923) as antacids in the stomach, but not as systemic alkalis. We have now had a considerable experience of their use in the treatment of ulcer. They appear to be just as efficacious as the usual alkalis, but I am not yet convinced that they may not also give rise to alkalosis even in the absence of pyloric obstruction and renal disorder. As the magnesium salt is slightly laxative and the calcium salt slightly constipating, the dose of the former can be increased when the patient is constipated and that of the latter reduced. In the uncommon cases in which there is a tendency to looseness of the bowels some of the magnesium salt should be replaced by the same dose of the calcium salt.

Greenwald stated that tertiary calcium phosphate had only one-fourth of the neutralizing power of the magnesium salt, which was equivalent to the same weight of sodium bicarbonate. But, using more accurate physico-chemical methods, Freezer, Gibson, and Matthews have shown that tribasic calcium phosphate is actually a slightly stronger alkali than the magnesium salt, but for practical purposes they can both be taken to neutralize about the same quantity of acid gastric juice as half of their weight of sodium bicarbonate.

ALKALOSIS

Sippy did not refer in any of his publications on the treatment of ulcer with large doses of alkalis to the toxic symptoms which occasionally develop. In 1923 Hardt and Rivers first drew attention to the subject and in 1925 Venables described seven cases of the kind observed at New Lodge Clinic. Curiously enough, no similar cases have been observed among my patients at Guy's Hospital, though an equal number have been treated in precisely the same manner.

According to Venables, toxic symptoms develop only in cases of duodenal ulcer as there was no case of gastric ulcer in our series. Hardt and Rivers stated that they occurred especially in patients with partial pyloric obstruction, who have in consequence continuous hypersecretion considerable quantities of acid being often lost by vomiting. But only in one of Venables's cases was there any evidence of pyloric obstruction and this patient was the only one who vomited severely.

In some of Hardt and Rivers's cases there was evidence of kidney disease before the symptoms developed, and in their two fatal cases an acute exacerbation of a chronic nephritis was found after death. On the other hand, only one of Venables's patients (a case of chronic prostatitis and cystitis) had a definite history of urinary disease, two others in Venables's series had a slight excess of blood urea before treatment was begun, the figure rising still higher at the end of a week's treatment. In the others no previous estimation of urea had been made, but in two the fall after the treatment had been discontinued was incomplete, so that perhaps some renal insufficiency had previously been present. In every case the blood urea was abnormally

high when estimated after the development of symptoms. The urine was only abnormal in the patient with old-standing cystitis and pyelitis, but in several cases reported by Hardt and Rivers albumin and casts appeared in the urine.

The symptoms generally appear within seven and almost always within fourteen days of commencing the alkaline treatment. Anorexia and depression are always present from the first, the patient being unduly introspective and nervous. He complains of difficulty in taking his milk, and after a time headache, nausea, and vomiting occur. He is irritable, and may complain of pruritus and dryness of the skin. Only in very exceptional cases do more severe symptoms develop. The patient then becomes apathetic and drowsy, and may finally become comatose. In two cases under Hardt and Rivers and in one of Venables's cases death ensued, but as a rule the symptoms never become very severe, and they rapidly disappear on discontinuing the alkali.

THE STOMACH TUBE

The stomach tube is useful in the treatment of two definite conditions—gastritis and pyloric obstruction. It should rarely, if ever, be employed unless one or other of those organic diseases has been definitely proved to be present.

(a) PYLORIC OBSTRUCTION

Increasing experience has shown how frequently the pyloric obstruction caused by an ulcer is due to oedema

(a)

(b)

CHART 3—Man aged 66 with only six months history twelve-hour gastric stasis (starch in resting juice) with hyperchlorhydria and hypersecretion—Chart (a)—secondary to duodenal ulcer. After fifteen days treatment with diet, atropine and evacuation by tube every evening the symptoms had gone and stasis and hypersecretion disappeared—Chart (b).

and congestion in its neighbourhood and reflex interference with the normal relaxation of the pyloric sphincter (achalasia) or pylorospasm. Consequently, when the ulcer heals the obstruction often disappears. If it persists, it is clear that it was from the first mainly due to cicatricial contraction, as a fibrous stricture is generally the result of many years of alternating activity and partial healing, so that its actual development during a course of medical treatment is very rarely observed. I have myself only seen this occur on a single occasion.

It has often been stated that when pyloric obstruction is sufficient to produce a six-hour residue after an opaque meal a gastro-jejunostomy should be performed without further delay. Our experience shows, however, that medical treatment may lead to the healing of an ulcer and disappearance of obstruction even if there is a twelve-hour residue, and even in exceptional cases a twenty-four-hour residue with peristalsis visible through the abdominal wall.

To obtain the most satisfactory results it is essential that the dietetic and medical treatment should be combined with evacuation of the stomach late in the evening in order to prevent the accumulation of very acid gastric juice, with or without food residue, which would otherwise occur during the night. Accordingly, in every case in which delayed evacuation has been shown to be present with the x rays and fractional test meals we use Senoran's

evacuator just before the patient settles for the night. It is only necessary to empty the stomach, no lavage is required. This can be done most satisfactorily if the last feed is taken three or four hours before the tube is passed. There is no reason why the patient should not have a small feed with a dose of atropine and alkali immediately afterwards, as a tube passed the following morning shows that food taken under these conditions is not retained abnormally long in the stomach. Evacuation is practised every night until not more than three ounces of food and gastric juice are present. When the ulcer has finally healed, the x rays and test meal show that evacuation takes place at the normal rate or with only slightly less rapidity than normal (Chart 3).

(b) GASTRITIS

Chronic gastritis is a not uncommon condition. It may be a sequel of acute gastritis caused by food poisoning or an acute infection. It may result from the constant irritation produced by excessive consumption of alcohol and to a less extent of indigestible and insufficiently chewed food, or from the swallowing of infective material from the mouth or nasopharynx. It can only be diagnosed by means of a fractional test meal, which shows excess of mucus in most or all of the fractions as well as in the resting juice. The thick tenacious mucus sticks to the surface of the mucous membrane and blocks the mouths of the gastric glands, so that only a small part of their secretion can gain access to the lumen of the stomach. At the same time the mucus acts as an alkali and combines with some or all of any free acid which reaches the food. Consequently, achlorhydria is often present, and in every case the quantity of free acid in the stomach is less than

(a)

(b)

(c)

CHART 4—Woman aged 53 with achlorhydria caused by chronic gastritis cured by lavage. (a) January 3rd 1928. Achlorhydria (b) January 6th. After preliminary lavage. (c) March 10th. After treatment with lavage but no lavage before test meal.

the normal for the individual. Hydrochloric acid is often given to patients with achlorhydria caused by gastritis, but it is generally not really required. If a second test meal is given after preliminary lavage, a normal curve of acidity is often obtained, when the achlorhydria persists it is due to true achylia, which is either constitutional, the gastritis being secondary, or the result of complete atrophy of the oxyntic cells following severe inflammation.

The main object of lavage in the treatment of gastritis is to remove the mucus sticking to the surface of the gastric mucous membrane. This can be done most efficiently in the early morning when the stomach contains no food. We have found that it is impossible to dislodge the mucus by ordinary water or by the sodium bicarbonate solution often employed. The only way in which the stomach can be washed completely free from mucus is by means of hydrogen peroxide, the bubbles of oxygen given off when it comes in contact with the mucus quickly dislodge it. It is necessary to begin with a weak solution— $\frac{1}{2}$ drachm to 1 pint—as otherwise the froth blocks the tube. A Senoran's evacuator is used, and lavage is continued until no more mucus appears, the stomach is then finally washed with water. The quantity of mucus is found to diminish very rapidly, and after a few days the strength of the hydrogen peroxide can be increased, as much less froth is produced. A strength of $\frac{1}{2}$ or 1 pint is finally used. When mucus is no longer present in the first washing the lavage is discontinued. A test meal given at this stage, which is

often reached ten or fourteen days and rarely more than a month after the beginning of treatment, shows that mucus is now absent from every fraction, and in most cases an average normal or even a high curve of acidity is obtained (Chart 4). If at the same time a diet similar to that I have already described as suitable for individuals with the ulcer diathesis but no active ulceration is given, and infective foci in the mouth and nasopharynx are treated, there is not likely to be any recurrence of the gastritis.

HYDROCHLORIC ACID

Achylia, or complete absence of free hydrochloric acid from the gastric contents, is a very common condition, it was present in no less than 15 per cent of 762 consecutive cases of abdominal disorder examined at New Lodge Clinic. It is important to decide whether it is due to inability of the gastric mucous membrane to secrete acid—true achylia gastrica—or to mechanical interference with the secretion and neutralization after secretion by excess of mucus in chronic gastritis. Whereas the former condition which is much the less common, should be treated by the administration of hydrochloric acid, the latter, as I have already pointed out, should be treated by lavage, which results in the gradual return of a normal gastric secretion.

Achylia gastrica is generally a familial and constitutional condition but it may also result from a single severe attack of acute gastritis or severe and prolonged chronic gastritis. In the former case it cannot be regarded as a disease, and, though it is present throughout life, it may never give rise to symptoms. In many cases, however, gastric symptoms develop sooner or later owing to the secondary gastritis which is likely to result from the loss of the diluting, softening, and antiseptic action of the gastric juice. Just as the food is prepared in the mouth for its reception in the stomach, so normally it is prepared in the stomach for its reception in the intestines. In achylia gastrica the food leaves the stomach in the same chemical and physical condition as that in which it enters; this often results in irritation of the intestinal mucous membrane, with the result that chronic or recurrent diarrhoea occurs. The absence of the antiseptic barrier offered by the normal gastric juice to swallowed bacteria and the abnormal alkalinity of the intestinal contents may result, as Knott has so clearly demonstrated, in intestinal infection. This is a factor of more or less importance in a large number of diseases, such as appendicitis, cholecystitis, and rheumatoid arthritis, it is probably the one essential predisposing cause of Addison's anaemia and subacute combined degeneration of the spinal cord.

It is clear, therefore, that the treatment of achylia gastrica is not only important for its direct effect on any gastric or intestinal symptoms to which it has given rise, but also in the prophylaxis and treatment of the various conditions I have just mentioned.

The treatment of achylia gastrica is a form of substitution therapy analogous to the treatment of myxoedema by thyroid gland and diabetes by insulin. It is, however, impossible in practice to provide anything approaching the quantity of acid secreted by a normal stomach. The dose often given is totally inadequate, but, if properly administered, it is easy to give as much as 2 drachms of dilute hydrochloric acid (B.P.) three times a day when mixed with half a pint of water; this dose provides a solution of approximately the same strength as normal gastric juice. If symptoms such as diarrhoea have developed as a result of hypochlorhydria, they often disappear at once with only a drachm or half a drachm of the dilute acid.

Though I fear I have been unable to record any recent advance in the treatment of gastric diseases of an epoch-making character, I think that some real progress has been made during the last few years in the treatment of functional gastric disorders and of two out of the three common organic diseases of the stomach—namely, gastritis and ulcer. There is no medical treatment of carcinoma, but the medical treatment of chronic gastritis and of chronic gastric ulcer may be regarded as a real prophylactic measure in preventing its development.

APPENDIX I

Ulcer Diet

1 Every alternate hour from 8 a.m. to 10 p.m. 5 oz. of milk. This can be warm or cold, and may be flavoured with tea.

2 Every other hour, alternating with 1, from 9 a.m. to 9 p.m. a 5 oz. feed, which may be made of any of the following: (a) arrowroot, cream of wheat, Benger's food, junket, custard to any of these red currant, apple, or other fruit jelly can be added, and the junket can be flavoured with chocolate. (b) at least two should consist of a thick white soup or semi-solid purée of potato, artichoke, cauliflower, or parsnip.

3 A rusk with butter should be eaten with three feeds.

4 1 oz. of cream should be added to the 11 a.m., 1 p.m., and 5 p.m. feeds, and $\frac{1}{2}$ oz. of olive oil should be taken before the 9 a.m., 2 p.m., and 7 p.m. feeds.

5 1 drachm of Mixture 1 with 1 drachm or more of emulsion of magnesia, according to the state of the bowels, should be added to each milk feed.

6 1 drachm of Mixture 2 should be taken before the 8 a.m. and 3 p.m. feeds, and 2 drachms before the 10 p.m. feed. The dose should be increased if no dryness of the mouth occurs.

7 1 drachm of tribasic magnesium or calcium phosphate should be taken after the 3, 7, and 10 p.m. feeds with a little water. An extra powder can be taken after any other feed during the day or night if any indigestion or heartburn occurs.

8 Wash the mouth out after each feed and thoroughly clean the tongue by scraping with a spatula morning and evening.

9 No smoking allowed during the strict treatment.

Note.—During the night the patient should have a feed with Mixture 1 by his bedside so that whenever he wakes whether in pain or not he can take a feed. This can be repeated as often as he is awake during the night.

Mixture 1

R. Sodium citrate	15 grains
Water	to 1 drachm

Mixture 2

R. Atropine sulphate	1/200 grain
Water	to 1 drachm

APPENDIX II

Post Ulcer Regime (To be followed permanently)

Avoid alcohol except, if desired later on, a small quantity of light wine or diluted whisky at meals, avoid effervescent drinks, avoid coffee.

Avoid all pits and skins of fruit (whether raw or cooked, or in jam and currants, raisins, and lemon peel in cake or puddings), nuts, and all unripe fruit. For example, an orange may be sucked but not eaten. Currants, raisins, and figs are particularly undesirable.

Avoid all raw vegetables, whether taken alone (celery, water cress) or in pickles or salad, green vegetables must be passed through a sieve and mixed with butter in the form of a purée. Porridge is only allowed if made with the finest oatmeal.

Avoid vinegar, lemon juice, sour fruit, spinach, pepper, mustard, curry, chutney, excess of salt, new bread, tough meat, salted fish or meat, pork, made up dishes, high game, clear or thick meat soup.

Take plenty of butter and cream and a tablespoonful of olive oil before each meal.

Eat slowly and chew very thoroughly.

Do not smoke excessively. No smoking at all if any indigestion present.

A meal or feed should be taken at intervals of not more than two and a half hours from waking till retiring and again if awake during the night. The feeds should, at first, consist of a glass of the following mixture, which should be prepared each morning: a quart of milk, 5 to 10 ounces of cream and 120 grains of sodium citrate in 1 ounce (more or less according to the state of the bowels) of emulsion of magnesia.

Have your teeth attended to by your dentist regularly every six months.

Take no drugs in tablet form.

If you have the slightest return of symptoms, go to bed for a few days on a strict diet, and do not wait for the symptoms to get serious.

THE RESULTS OF SURGICAL TREATMENT OF GASTRIC AND DUODENAL ULCER.

BY

A J WALTON, M.S., F.R.C.S.,
SURGEON TO THE LONDON HOSPITAL

AN accurate estimation of the comparative values of the different methods of treatment of gastric and duodenal ulceration is fraught with considerable difficulty, and this chiefly owing to the fact that a search is being made for an impossible formula giving the mathematical results of a handicraft. Surgeons make the grave error of comparing the results of a method as executed by one surgeon with those of another performed by a second surgeon, forgetful of the fact that the cases may be in no way comparable, and that the results are entirely dependent upon the extent to which an individual surgeon has perfected his own method. Physicians fall into an equal or a greater error, in that they estimate the results of surgical treatment from the failures that fall into their hands, when they are ignorant of the technique of the operation that was carried out, and have no knowledge of what percentage these failures represent of the total number of operations. The multitudinous statistics that have been published are also in no way comparable. In some published lists the after-results have been traced for only one year, or short after-results have been combined with the figures of cases traced for a longer period. In some the percentage of good results is computed from the total cases, in others, only from those that have been traced. In a recent paper, for instance, the author publishes a table giving 90 per cent of satisfactory results after partial gastrectomy, but his figures do not include those patients who died, 92 per cent. For these reasons the beginner is hopelessly confused, and finds it almost impossible to determine which operation he ought to undertake and practise for the different lesions. The method adopted by the British Medical Association in their combined investigation does much to overcome this latter difficulty, for the only cases which are investigated are those which were operated upon in the years 1920-24 inclusive, and when published these figures should be so arranged that all cases are included and the percentages of good and bad results computed on the total number. It is to be hoped that large numbers of cases will be collected, so that they will form a basis for comparison with the results of other methods of treatment. Such a statistical investigation is specially required of the late results of medical treatment, for until recently very little had been published in this respect. The figures of Dr. David Smith of the end-results of 214 cases treated medically from 1913 to 1922¹ do much to fill this want, and form a useful basis with which the results of surgical treatment may be compared. The immediate results showed 67 per cent of males and 76 per cent of females cured, with an immediate mortality of 2 and 5 per cent respectively. It was, however, interesting to note that if the symptoms had persisted for more than ten years only 25 per cent of each sex were cured by medical treatment. The important figures, moreover, were those of the end-results of cases treated for five to fifteen years. These showed in the males 29 per cent cured, 15 per cent improved, 31 per cent failures, and 19 per cent of deaths, in the females 40 per cent cured, 20 per cent improved, 25 per cent of failures, and 15 per cent of deaths. It is also necessary to note that in this period 5 of the cases developed carcinoma. The importance of these figures lies in the fact that the cases have been traced for a considerable period, for in so many of the reports of the results of medical treatment the cases have been followed only for a short period, often, indeed, for no longer than the periods of remission which are normally seen in the symptoms of untreated patients with gastric or duodenal ulceration.

In presenting the figures of the end-results of my own cases treated in these years (1920-24) attention must be directed to the fact that they only represent the results of the operation as performed by an individual surgeon, for

just as one carpenter carries out the greater part of his work with a saw, while another obtains better results with the use of a chisel, so is it possible that for certain ulcers one surgeon will obtain the best immediate and end results by the use of gastro-enterostomy, and another by the performance of a partial gastrectomy. To this fact insufficient attention has been paid in the many papers that have been written attempting to prove that one or other method is the best form of treatment. Since, however, statistical papers of this sort should be published with the idea of helping beginners in their choice of technique, it will be useful to indicate the reasons why it is considered that the selected operation is likely to give the best results in the hands of the majority of surgeons who have not assiduously practised and become exceptionally skilled in the use of any one method, for there is no doubt that to-day many surgeons are publishing remarkably good results which are due, not to the use of the method they advocate, but to the fact that they themselves have become skilled to an unusual degree in the use of that method.

PYLORIC AND DUODENAL ULCERS

Of the three more commonly performed operations for this type of lesion—(1) gastro-duodenostomy with or without excision, (2) gastro-enterostomy with or without embedding the ulcer, (3) partial gastrectomy—I have always selected as the routine operation gastro-enterostomy with embedding the ulcer. The latter step is performed by so widely embedding the ulcer with a running mattress suture of silk that the pylorus or first part of the duodenum is completely occluded. Later investigations with x rays after an opaque meal show that it becomes patent again in six to eight weeks. A full discussion of the relative values of these different operative procedures is beyond the scope of this article, but it is sufficient to say that the chief objection which has been raised by others to the routine use of gastro-enterostomy is the alleged frequency of the later development of gastro-jejunal ulceration. Von Haberer and others believe that this complication is specially likely to occur if the pylorus be occluded. This danger has been, in my experience, as I think my figures will show, considerably exaggerated, possibly because I only make use of a temporary occlusion. In my own hands this operation has shown a low immediate mortality and a very high percentage of late cures. Partial gastrectomy in my hands, and I believe also in the hands of all who have not practised it in a large number of cases, gives a higher immediate mortality. I have therefore reserved its use for those cases where there was doubt, however slight, of the presence of carcinoma, and as a later measure for the few cases that have developed gastro-jejunal ulceration. The actual figures of my ulcers obtained in this group are shown in Table I, A.

Of the total of 172 cases only 25 were females.

Mortality—In this relatively early series there were 4 deaths—that is, 2.3 per cent. This can and should be considerably reduced. In my later cases there have now been 180 consecutive operations of this nature for uncomplicated pyloric and duodenal ulcers without a death.

Gastro-jejunal Ulceration—This complication occurred in 6 cases (3.4 per cent), and the figures stress the point to which attention has often been drawn that it is a complication almost wholly limited to pyloric and duodenal ulceration there being only one unusual example among the lesser curve ulcers. Thus of the total number of 280 cases in this series there were 7 of gastro-jejunal ulcers (2.5 per cent). Even this is somewhat higher than is seen in larger series. In the total cases operated upon up to February 1927—that is, eighteen months ago—there were 831 chronic ulcers, 15 of which showed gastro-jejunal ulceration, a total incidence of 1.8 per cent.

Carcinoma—It is of interest to note that in no case has carcinoma developed as a late complication so that the claim that partial gastrectomy should be performed to prevent this lesion is unsubstantiated for this group of cases.

Recurrent Ulcers—In one case an ulcer developed on the lesser curve after a pyloric lesion had been cured by gastro-enterostomy.

Satisfactory Results—Many figures that have been published from time to time claim to prove that the end results of this method of treatment are unsatisfactory but this series shows 85.5 per cent satisfactory results for the pyloric ulcers and 81.9 per cent of the total number. If the 3 cases of pyloric ulcer and the 4 cases of duodenal ulcer which could not be traced are eliminated from the series the percentage figures become 90.6 per cent and 88.4 per cent respectively. The standard of recovery is high these patients being free from symptoms able to take a full diet and capable of performing the usual duties of life, which in many cases were of a most arduous and exacting nature.

Four of the patients died at a later period all from some condition unconnected with the ulcer, and since at the time of their deaths they were quite free from all gastric symptoms they have been included among those considered to be cured. The figures of the few cases in which anterior gastro-enterostomy or partial gastrectomy were performed are shown in Table I B and C.

LESSER CURVE ULCERS

In many of the reported series this type of ulcer has not been differentiated from the pyloric. The issue is thereby considerably confused, for whereas many observers have obtained extremely good results with gastro-enterostomy for pyloro-duodenal ulcers, the majority have appreciated the fact that not only does this operation fail to cure lesser curve ulcers—especially if adherent—in some 50 to 60 per cent of the cases, but sometimes a lesser curve ulcer actually develops after the gastro-enterostomy has been performed for the pyloric lesion. In my total cases up to February, 1927, this was seen in 8 patients, in 6 of whom the gastro-enterostomy had been performed by other surgeons and in 2 cases by myself. One of these cases occurs in the 1920-24 series (see Table I, A). On the other hand, local removal of the ulcer alone has in the hands of nearly all surgeons given poor results, a local recurrence taking place in a high percentage of cases. Therefore the operations of choice to-day are (1) some form of local excision by knife or cautery combined with gastro-enterostomy and perhaps with occlusion of the pylorus (2) partial gastrectomy.

It is for this type of lesion especially that the majority of Continental surgeons advocate partial gastrectomy, but there is considerable divergence of opinion as to which

method should be chosen. Schoemaker, by the use of his special technique, removes a large portion of the lesser curve and a smaller portion of the greater curve, others use the Polya or Balfour method, while of late some have abandoned the Polya and returned to the Billroth I method, von Haberer stating that in his experience the Polya operation was unsatisfactory owing to the large number of gastro-jejunal ulcers which followed its use. It is in the choice of these various technical steps that the question should be so largely personal, the figures of the advocates of the different methods not being comparable, for the surgeon who performs gastrectomy for all, including simple cases, will have a low mortality, and he who uses it only for large adherent ulcers will have a high mortality. My preference has always been for local excision with the knife followed by temporary pyloric occlusion and transverse gastro-enterostomy, the latter opening running parallel with and close to the greater curvature, for in my experience this method has given a lower mortality and is remarkably free from ill after-results. The risk of gastro-jejunal ulceration at a later date is almost negligible. In my total series of 278 lesser curve ulcers analysed up to February 1927, gastro-jejunal ulcer occurred only in one exceptional case which fell into this 1920-24 series. Although partial gastrectomy has up to date been found to give exceptionally good results, the removal of three-quarters or more of the viscus for an ulcer, often only 1 cm in diameter, seems an unnecessarily severe and deforming operation. Though no examples have fallen to my experience, Hurst warns us of the danger of pernicious anaemia following the more extensive gastrectomies. For these reasons it has been my routine to excise the ulcers

locally, but wherever there is the slightest possibility of carcinoma, as suggested by the symptoms, by the test meal, or by the x rays, a partial gastrectomy has been performed. With certain large adherent ulcers not only is the danger of carcinoma greater, but a partial gastrectomy becomes the easier operation, and thus has been chosen as throwing a less severe strain upon a patient often enfeebled by prolonged and severe symptoms. The end-results of wedge resection with gastro-enterostomy and temporary occlusion of the pylorus is seen in Table II, A.

Of the total of 67 cases 51 were males and 16 females, a point of interest as many observers have found this type of ulcer to be more common in females.

Mortality—Two of the patients died as the direct result of the operation, giving a mortality of 2.9 per cent.

Gastro-junal Ulcer—In only one unusual case did a gastro-junal ulcer develop. This patient, a male, had a high pre-operative acidity of 0.23 per cent, but there was no concomitant ulceration of the pylorus or duodenum. There was also one recurrence at the site of excision, a complication for which no explanation could be found. No silk suture was used, and there had been no post-operative haematemesis.

Carcinoma—In no case in this series did carcinoma follow the operation and therefore the statement that a wedge resection is unsatisfactory in that an insufficient amount is removed to prevent the possibility of the after-development of carcinoma, is unsubstantiated.

Satisfactory Results—Fifty nine of the patients have remained well being able to eat any food and to live a normal life. They form 88 per cent of the total or, if we exclude entirely from the series 3 cases that have not been traced there are 92.18 per cent of cures.

These figures and those for pyloric and duodenal ulcer compare very favourably with the results of medical treatment as published by Dr Smith. Included with the 59 cases are 3 of the 4 deaths which occurred late after

operation, the death in these cases being due to an entirely separate lesion and the patients being quite free from all gastric symptoms at the time of their demise. It will be seen from Table II, B, that only one case in this series was treated by enteric excision, and the results are not satisfactory, the patient still suffering from some gastric symptoms. The results obtained by partial gastrectomy or gastro-enterostomy alone are shown in Table II, C and D.

Hour Glass Stomach

The number of cases of hour-glass stomach treated in the short period 1920-24 are too small to lead in themselves to any accurate conclusion. It is generally realized, however, that all the older methods which aim simply at overcoming the deformity are unsatisfactory, as they leave untouched the active ulcer on the lesser curve. Treatment must always be aimed at curing this active ulcer, which is associated with the scarring and often with a second stenosing ulcer at the pylorus. Just as with a simple lesser curve ulcer, it has been my practice, wherever possible, to treat these cases by wedge resection, the wedge being made with a very wide base, so that when the opening is sutured the constriction is overcome. This is combined with gastro-enterostomy and temporary pyloric occlusion. In certain cases, however, where the isthmus is very narrow, this procedure is not possible, and a partial gastrectomy is then performed. The results of these procedures in the small groups falling into the time period are seen in Table III, there being 80 per cent of satisfactory results.

GASTRIC AND DUODENAL ULCER:

AN ANALYSIS OF 200 CASES TREATED BY OPERATION

BY

L. R. BROSTER, O.B.E., D.M., M.Ch.,
F.R.C.S.

ASSISTANT SURGEON CHARIKRO CROSS HOSPITAL, SURGEON TO THE
QUEEN'S HOSPITAL FOR CHILDREN

AROUND this subject a formidable literature is accumulating. Fortunately the acrimonious controversy which hitherto has raged is shifting from the barren grounds of invidious comparisons between surgical and medical treatment to a more stable statement of facts from both sides. Opinion is becoming more crystallized, and there is now a general agreement that immediate surgery, except for the complications of perforation and possibly haemorrhage, has no place in its treatment, and should only be resorted to after medical treatment has been given a fair but not too lasting trial. Surgery has an undisputed application to all those cases of mechanical defect from the contraction of ulcers, such as duodenal and pyloric stenosis and hour-glass deformity, and also to those cases of deep ulceration involving adherence or penetration of surrounding structures, and suspected early malignancy. In no less equivocal way should medical treatment be devoted to the cure of ulcer in its early stages. This unanimity of opinion, however, does not apply to a large number of cases, which fall into the following groups: (1) cases which have recurred after medical treatment, (2) cases in which there has been recurrent or dangerous haemorrhage after medical treatment. Finally, there is a group of cases in which treatment depends upon the habits and economic or social position of the patient. Some of these eschew operative intervention, others, who will not co-operate or find medical treatment irksome, demand it.

It would seem that any controversy on the subject should be concentrated on those unknown factors of this disease which inflict much suffering on, and severely handicap, a certain section of the community. So far there is a lack of finality on its etiology. Surgery has been foremost in placing our knowledge on its present foundations, chiefly because its results can be checked and analysed, and endo-

logy has earned no mean niche in the elucidation of the problem.

This paper represents an analysis of a series of some 200 cases, which have been treated in the ordinary routine way in the surgical wards of the Charing Cross Hospital. They include the results of a previous series published in this *Journal* in 1926 (vol. 1, p. 936), and belong mainly to Mr. H. S. Clogg and myself. Statistics frequently have a doubtful value, especially if they have a definite case to establish, and vary in the manner of their compilation. They must, however, necessarily serve as the basis of a standard of comparison, and their intrinsic value belongs to the individual, in that they enable him to record his progress. Problems which present themselves in the daily routine of hospital work are apt to pass unnoticed, and can only be rectified and adjusted in their true perspective by the analysis of numerous cases. Unless a surgeon is content to review his work thus he is apt to sacrifice his sense of value judgment.

There has been no selection of cases in this series, the patients have been operated upon and treated according to the facilities provided by a general hospital. The results do not quite reach the high standards which have been published by some authorities, but they do represent a fair estimate of hospital routine work. There is no doubt that they can be improved. Large draughty wards and the constant changing of assistants, sisters, and nurses—all necessary features of a teaching and training institution—do militate against that even flow of team work which is so necessary to the welfare of these patients.

ETIOLOGY

The opinion has long been held that chronic infection is a direct cause of ulceration, and that it is necessary to eradicate any focal sepsis before attempting to deal with the ulcer, on the assumption that it provokes the periodic recrudescence of the symptoms which is so characteristic a feature of the clinical history. In some cases the infective agent reaches the stomach direct. It is therefore necessary to eliminate infective lesions of the gums, tonsils, and nasal accessory sinuses. Pannett considers, however, that ulceration is caused by some specific organism (not yet identified) which reaches the stomach by this route, and

not by the various pyogenic organisms which have been from time to time cultivated from ulcers

In other cases it is believed that infection reaches the stomach by way of the blood and lymphatic streams. It is assumed that bacterial emboli are carried to the region of the pylorus and lesser curve, and as a result of septic infarction cause devitalization of the stomach mucosa and render it a prey to gastric digestion. This theory receives support from the fact that chronic infective lesions are continually being found co-existing with ulceration. The more common of these are apical abscesses, lesions of the gall-bladder, appendix, Fallopian tube, and kidney. The Leeds school has pointed out that it is probable that infection is carried along the lymph channels from the right iliac fossa.

The feature of these ulcers is that they not only exist in an environment of gastric juice, but predominate in certain sites—for example, on either side of the pylorus and along the lesser curve. Traumatic and operative wounds of the stomach heal quite readily, the latter are normally healed in ten days. Therefore in the evolution of an ulcer there must be some factor at work which primarily delays healing, and this factor takes considerable time to act and may keep on acting. The pathologists tell us that histologically these ulcers are separate entities, and that they occur as the result of a true digestive process. The physiologists are still uncertain of the series of changes which regulate the acidity of the stomach and the action of the pyloric sphincter. Bolton and Goodhart have advanced the view that, "when the percentage of acidity of the digesting stomach content reaches a certain average height regurgitation of duodenal contents occurs, and brings down the acid curve by neutralization." This regurgitation is permitted by the relaxation of the pyloric sphincter. To what extent this takes place is not definitely established. Bile should be a common content of the test meal, but this has not been the case in this series. On this assumption it is possible to explain the peculiar selective origin of ulcers that they occur in the zone of interaction between the hydrochloric acid-pepsin juice and the alkaline duodenal contents. When relaxation is active interaction takes place along the lesser curve, and where the pylorus is hypertonic mixing only occurs in the duodenum. The inception of the ulcerative process would take place where these two streams meet, and in a spot where the anti-bactericidal properties of the acid juice have been lessened. On these grounds it would be justifiable to surmise that this zone of interaction is not always a fixed one and that the exacerbations of the ulcerative process only take place when the two synchronize. From the practical standpoint the only three cases of jejunal ulcer in my own personal series would tend to support this. In each case the ulcer was found at the left-hand corner of the anastomosis, which in a posterior gastro-entrostomy would correspond to the nearest point on the lesser curve where the acid and alkaline juices meet.

CLINICAL FEATURES

Although focal sepsis is found to exist in a certain number of cases there are others in which no such cause can be detected. Certain characteristics are found in the majority of cases, but it cannot be said that they are so universal as to constitute an ulcer diathesis. The most typical case is that of an active middle-aged man, rather lean and tall with strained expression, slight mental irritability who tends to become grey prematurely. The predilection for the male sex is seen in the following figures:

	Male	Female
Duodenal ulcer	82%	18%
Pyloric ulcer	91%	9%
Gastric ulcer	75%	25%

This marked affinity for the male has been variously ascribed to differences in his habits—smoking irregular and heavy meals, an increased consumption of alcohol and meat food, all probably causing pyloric hypertension, 86 per cent. these ulcers were on one or other side of the pylorus in males, whereas the incidence of gastric ulcer in females is appreciably higher. Spasticity of the pylorus prevents duodenal regurgitation and alkalization of the

stomach content, yet acid in the duodenum is necessary for the normal closing of the sphincter. Pyloric irritability, we are told, is increased by local disease (ulcer) and irritability of the central nervous system (often reflex), whereas spasm is excited by food irritation, either mechanical or chemical, or by hydrochloric acid. It seems that on this subject we are revolving round a vicious circle, and require further work to clear up a confusing situation.

Tyrrrell Gray has drawn attention to the causal relationship between smoking and ulceration. It would seem that the habitual empty-stomach smoker would be more likely to be affected, and if this is so, we ought to expect in the future an increased incidence of ulcer in women.

With regard to age incidence, the majority of ulcers have been operated upon in the third and fourth decades, with an appreciable increase into the fifth decade for women.

SYMPTOMATOLOGY

It is the experience of all of us to find difficulty in interpreting the symptoms on purely clinical grounds. Although we are wont to associate a standard syndrome with certain types of case its application is by no means universal. The diagnosis of ulcer is based upon pain, vomiting, and haemorrhage. Of these the most important is pain, which is characterized by its periodicity. 99 per cent have complained of it in this series, and it was absent in only three cases—one duodenal ulcer, and two gastric ulcers. Bouts of pain lasting for days or weeks are followed by periods of complete freedom which may continue for months. This intermittency has occurred in over 75 per cent of the cases. In under 10 per cent has the pain been constant, in a smaller percentage the pain has been intermittent at first and constant later. In the cases of pyloric ulcer this later constant pain has run *pari passu* with the decrease in the intermittency.

In the majority of cases pain bears a definite relationship to food. Seldom coming on before half an hour after food, it may appear any time during the interval before the next meal. As a general rule the more distal the ulcer is from the cardia the later the pain appears. The average onset in this series has been as follows:

Duodenal ulcers	Between 2 and 3 hours
Gastric ulcers	1 and 2 "
Pyloric ulcers	1 and 3 "

In only a small percentage of cases has the pain been unrelated to food and in a smaller percentage has it occurred within half an hour after food. For the relief of pain patients often devise different methods. The majority of duodenal ulcers are relieved by taking more food, whereas the gastric and pyloric ulcers obtain most relief after vomiting.

Vomiting is only of importance from its association with pain. It usually occurs when the pain is at its height, and brings with it relief. A relative idea of its frequency is seen in the following table:

Duodenal ulcer	50%
Gastric ulcer	88%
Pyloric ulcer	70%

Its diagnostic value increases in such conditions as pyloric stenosis and hour-glass stomach by its time of onset, amount, and content.

Haemorrhage, whether in the form of haematemesis, melaena, or both, always adds risk to the patient, responsibility to the practitioner, and a higher mortality rate to the surgeon. Its grosser forms are shown in the following table:

	Haema-temesis	Melaena	Haemorrhage and Melaena
	Per cent	Per cent	Per cent
Duodenal ulcer	6	25	11
Gastric ulcer	24	7	14
Pyloric ulcer	7	21	7

No systematic investigations were undertaken for occult blood. These cases have been treated medically at the time of the haemorrhage, and operation, with an occasional transfusion, has been undertaken during quiescent

intervals. Of the fourteen immediate deaths eight had suffered from haemorrhage, and there is no doubt that it is an indication for earlier operation.

DIAGNOSIS

Although a dependable diagnosis can be made in a large number of cases on the history alone, we now have in radiology a most reliable source of information. In atypical cases it should never be neglected. It has been my practice to pursue this form of investigation in all cases of dyspepsia which recur or do not respond to medical treatment, and in all cases of ulcer. In the latter it often fortifies the surgeon with the knowledge of a co-existing ulcer, and with a preconceived plan of operation. To obtain the best results it is essential to collaborate with the radiologist, and in this respect I have been particularly fortunate in receiving much help and co-operation from my colleagues Dr. Russell Reynolds and Dr. S. Cochran Shanks. Since the installation of a new x-ray plant in the hospital the results have been most gratifying. The following table shows the x-ray report checked by the operative findings.

	No. of Cases	Correct	Wrong	Misplaced Ulcers
Duodenal ulcer	39	30	6	3
Gastric ulcer	23	17	2	8
Pyloric ulcer...	20	1	1	—

Under the heading of misplaced ulcers I have classified those reports in which, although an organic lesion was indicated, the lesion did not correspond to the actual site of the ulcer.

The notable difficulty seems to be the differentiation of lesser curve from duodenal ulcers. In the duodenal ulcers two were reported as lesser curve ulcers, and one as a gastric ulcer with delay. Of the eight in the gastric series, five lesser curve ulcers were reported as pyloric ulcers, one as a duodenal ulcer, one as a seven-hour delay, and one ulcer on the posterior pyloric wall as a carcinoma. The one wrong report of the pyloric series was masked by the presence of gall stones.

It is interesting to find that the point raised in a previous communication on this subject, that the posterior ulcer is difficult to identify, has not obtained in this series.

Unusual features were present as follows:

Among the duodenal ulcers a lesser curve ulcer developed three years after gastro-enterostomy.

Among the gastric ulcers a lesser curve ulcer was coexisting with a duodenal ulcer, and a case of lesser curve ulcer subsequently developed a duodenal ulcer.

Multiple ulcers were distributed as follows:

Double duodenal ulcer	1 case
Double pyloric ulcer	1
Multiple gastric ulcers	2 cases
Antero-posterior lesser curve ulcers	2
A lesser curve and a greater curve ulcer	1 case
Antero-posterior pyloric ulcer	1 "

Test Meals

Although test meals have not been given as a routine in these cases, they nevertheless have a definite value. From the diagnostic point of view they have been disappointing, especially in cases of gastric ulcer, and the results have shown a wide variation.

In cases of duodenal ulcer the tests performed by Mr. Jocelyn Patterson have been extraordinarily accurate, and when other evidence is conflicting a sustained hyperchlorhydria often indicates the true diagnosis. In cases of carcinoma the low acid content is of great help.

The chief aid rendered by the test meal is that of guidance for treatment. Cases of the penetrating type of duodenal ulcer associated with surrounding oedema, and with an abnormally high and sustained acid curve, are regarded with suspicion. There is a strong impression that these cases are unsuitable for gastro-enterostomy alone, owing to the fact that they are liable to develop jejunal ulcers.

OPERATIVE PROCEDURES

Without being wedded to any particular type of operation, and with an open and inquiring mind as to which type of operation is best suited for individual cases, the following operations have been performed in this series, in the main by Mr. H. S. Clogg and myself. The average duration of symptoms has been six and a half years, some have been poor operative risks, others have had complications dealt with at the same time, and others have been re-operated upon.

Type of Ulcer	No of Cases	Posterior Gastro-enterostomy	Posterior Gastro-enterostomy plus—				Partial Gastrostomy	Sleeve Resection	Anterior Gastro-enterostomy	Gastro-jejunostomy
			Ulcer Infolded	Ulcer Excised	Appendicectomy	Cholecystectomy				
Duodenal	87	Total 79	15	2	27	3	4	—	4	—
Gastric	76	33	4	8	13	2	27	6	2	2
Pyloric	44	35	4	1*	15	2	7	—	—	—
Totals	207	154	24	11	55	7	33	6	6	2

* Excision only.

The immediate mortality was 14 or 6.7 per cent.

Duodenal ulcer	4 or 4.6	"
Gastric ulcer	6 or 8.0	"
Pyloric ulcer	4 or 8.8	"

Of these 14 cases 8 had had haemorrhage either as haematemesis or melaena.

The later mortality shows that 2 patients died from carcinoma, 1 from lymphatic leukaemia, and 3 as a result of re-operation.

Of the deaths in hospital 6 were due to chest complications, 7 were not stated, 1 was from weakness and anaemia after haemorrhage, 5 were cases of partial gastrectomy, 7 were posterior gastro-enterostomy cases, 1 sleeve resection, and 1 anterior gastro-enterostomy.

RESULTS

All these patients have been written to, and replies have been received from 121. The oldest cases range from seven years, and no case under one year is included.

The following method of assessing the results has been followed, it is based upon the replies from patients or their doctors.

Very Good. Patients showing very marked improvement, have no pain, have gained weight, are at work, and able to eat anything.

Good. Patients who have improved, have no pain, have gained weight, are at work, and able to eat anything, but show a distaste for one or two items of food.

Very Fair. Patients who have improved, but get occasional pain, fullness, and flatulence when over-indulgent with regard to their diet. Their weight is constant and they are at work.

Fair. Patients with subsequent attacks of pain or haemorrhage which have necessitated medical treatment. Some are at work or doing light work.

Poor. Patients in whom operation has been of no benefit and are not able to work. Recurrence or gastro-jejunal ulceration obtained in some of them.

Type of Ulcer	No. of Cases	Very Good	Good	Very Fair	Fair	Poor
		Per cent.	Per cent.	Per cent.	Per cent.	Per cent.
Duodenal	58	30	44	8.6	8.6	8.5
Gastric	39	28	14	12.5	2.5	2.5
Pyloric	24	33	41.7	7.9	12.5	4.0
Total	121	32	47	10	7.8	5

A further analysis of the very good and good cases shows that the total average cure without a relapse for the whole series is 3.3 years, and the average for the gastric and duodenal ulcers separately is the same figure. It would appear from these figures that once a satisfactory result from operation is obtained there is no tendency to recurrence.

From the above it will be seen that about 80 per cent may be regarded as cured, about 10 per cent as improved, and about 12 per cent as receiving little or no relief. It is interesting to compare these results with those from individual operations.

	Very Good	Good	Very Fair	Fair	Poor
Partial gastrectomy	3	9	1	1	1
Excision with posterior gastro-enterostomy	3	—	2*	1	1
Sleeve resection	3	—	—	—	—
Posterior gastro-enterostomy—					
For gastric and pyloric ulcer	13	18	—	4	—
For duodenal ulcer	15	25†	5*	3	4
Total (112 cases)	37	52	8	9	6
Percentage	33	46.4	7	8	5

* One with gall stones † Two with gall-stones

The good results from partial gastrectomy amount to 80 per cent, from posterior gastro-enterostomy in gastric ulcer to 89 per cent, in duodenal ulcer to 77 per cent, the combined average from posterior gastro-enterostomy works out much the same as that for partial gastrectomy—that is, 80 per cent.

In this series there have been 6 cases of jejunal ulcer, which agrees with the percentage published by many other observers.

These results, if they suffer by comparison with the results published by other surgeons, are a fair criterion of the treatment which can be expected by the patients from a general hospital, in which it is impossible to cater for individual cases. Measures of improvement are easier to discern than to carry out. Patients are apt to regard operation as a panacea for their ills and a happy release from the toils of medical treatment. Being wage-earners they often have not the time to attend hospital for further advice, and the dietary indiscretions in spite of instruction are often alarming. An inquiry into this subject shows in a general way that pork, beef, and pastry are the main items of disagreement, and it is interesting to note that pastry and carbohydrates upset the duodenal ulcers, whereas the proteins (pork, beef, mutton, bacon, veal) disagree with the gastric ulcers. Fried and recooked foods, fruits, vegetables, condiments, cheese, eggs, cream, milk, and alcohol all appear on the list, with a slight bias against the duodenal ulcers.

I am extremely indebted to Mr H. S. Clogg for his kindness in allowing me to publish his cases and for his very helpful criticisms and guidance.

A CASE OF EXTENSIVE PULMONARY EMBOLISM FOLLOWING FRACTURE

BY

V. COTTON CORNWALL, M.B. CH.B. LIVERP.,
M.R.C.S. L.R.C.P.

AND

C. W. PONDER, M.A. M.D., D.P.H.
M.R.C.S. L.R.C.P.

ASSISTANT COUNTY MEDICAL OFFICER KENT AND COUNTY PATHOLOGIST

With a Note by

W. HOWEL EVANS, M.B., B.Sc.,
LECTURER IN PATHOLOGY, UNIVERSITY OF LIVERPOOL

The following case appears worth recording.

Mrs. V. aged 43, was seen by one of us (V.C.C.) suffering from a fractured left tibia and fibula (fracture en bloc) and sent into hospital, when the limb was fixed in plaster-of-Paris. She was discharged two weeks later, and the district nurse (who is not a trained masseuse) attended to massage the limb, but a doctor was not called in.

Six weeks after the accident one of us (V.C.C.) was asked to examine the limb. Union appeared perfect and there was no shortening of the leg; there was a moderate

amount of oedema of ankle and leg to the knee, but no varicosity of the superficial veins. The ankle and knee, which were very stiff, were forcibly moved through a few degrees, and the nurse was instructed how to massage and move the limb, the patient was given permission to walk on crutches. She stated that she was being sick, but there was no discoverable cause, and she did not look ill. A sedative alkaline mixture was given, and it was reported that the sickness ceased the same day, and that the patient ate normally afterwards until the time of her death two days later.

At midday on the day of death she asked her companion not to leave her, and requested to be helped out of bed. Almost immediately afterwards she wanted to return, and had hardly been helped back when she gave a slight groan and rolled on to her right side. She then gave another groan, rolled on to her back, and expired. When seen about two hours later she was lying on her back with mouth slightly open and a peaceful expression on her face.

Post mortem Examination

Externally nothing abnormal was found except that the neck appeared unduly movable.

Internal examination. Cervical vertebrae normal and no fracture of cranial bones, brain and abdominal viscera normal, diaphragm contracted, lungs appeared normal, but did not fill the thorax, the heart was contracted and appeared normal.

The heart and lungs were removed and dissected out (C.W.P.). On opening the right ventricle and pulmonary artery a long clot of about the size of the lumen of the internal iliac vein was found. This had evidently folded itself so that two ends were passing into the right branch of the pulmonary artery, and two into the left thus preventing the blood flow to the lungs and producing sudden death. The clot could not be extracted by traction. There was also a free end pointing to the pulmonary valve. The clot as it originally reached the heart must have been several inches long.

Diagram to show position of the large embolus when pulmonary artery had been opened.

Internal iliac vein was found. This had evidently folded itself so that two ends were passing into the right branch of the pulmonary artery, and two into the left thus preventing the blood flow to the lungs and producing sudden death. The clot could not be extracted by traction. There was also a free end pointing to the pulmonary valve. The clot as it originally reached the heart must have been several inches long.

Pathological Report

The specimen was sent to Professor Ernest Glynn for further examination, and in his absence Dr. Howell Evans has kindly commented as follows:

Sections have been cut from the clot in the right ventricle and from clots found in the branches of the pulmonary artery near the periphery of the lungs.

Dissection of the main branches of the pulmonary artery traced into each pulmonary lobe showed firm clot in many of these particularly in the lower lobe.

1. Clot from ventricle shows distinct lamination and very marked pigmentation. It is obviously *ante mortem* and the appearances suggest that it is a few weeks old.

2. Clot from pulmonary artery, left base shows an appearance almost identical with right. The lung is somewhat collapsed and the bronchial cartilages show slight staining with blood pigment.

3. The clot in this branch of the pulmonary artery is more recent and not laminated but shows well marked pigmentation. The suggestion arising from these three sections is that Nos. 1 and 2 are of some weeks' duration but No. 3 perhaps only a few days.

The specimen raises the question of pulmonary thrombosis or pulmonary embolism. As you know Professor Glynn has for years urged that many cases arose from primary thrombosis in the lung itself. The best evidence of embolism is to find as many sometimes be done a thrombus in a systemic vein which might have given off the embolus. My personal opinion is that the whole process is due to a change in the blood and we have evidence that the most important demonstrable change is the increase in the blood platelets which occurs after operation or after fractures. This means to say that the blood might clot at any given point and I suspect that frequently there is a contemporaneous clotting both in the lung and in a systemic

vein. The present specimen, I believe, shows this point. I cannot help thinking but that the coiled up clot in the heart came from a systemic vein, yet one finds evidence of quite definite *ante mortem* clotting in branches of the pulmonary arteries.

Discussion

The features of this case are

- 1 The lack of proper massago and movement, thus favouring stasis of the blood, which many workers have shown tends towards thrombosis.¹
- 2 The lack of evidence of thrombo-phlebitis before the embolism occurred.
- 3 The length of time which the patient lived, presumably with this large foreign body thrashing about in the heart, the only symptoms being the sickness and the vague feeling of something wrong.
- 4 The remarkable size of the clot.

SOME OBSERVATIONS ON THE ERYTHROCYTE

WITH SPECIAL REFERENCE TO PUNCTATE BASOPHILIA,
DIFFUSE POLYCHROMASIA, AND RETICULATION

BY

W E COOKE, M.D., F.R.C.P.E.D., M.R.C.P.
(From the Pathological Department Wigan Infirmary)

FROM the time that Ehrlich (1885) noted the three distinct basophilic conditions in erythrocytes controversies have waged on their character and significance, but for many years the trend of opinion has been towards the view that punctate basophilia, diffuse polychromasia, and reticulation are expressions of the same process.

Cesaris-Demel (1907) concluded that punctate basophilia and reticulation were identical, and Key (1921) agreed that the basophilic substance in the three conditions was the same. Brookfield (1928) believes that the stippled cells in lead poisoning are immature cells (reticulocytes and polychromatic cells) altered by the toxic action of lead. His

FIG 1.—Erythrocytes showing spongioplasm after the lipid membrane has been altered or dissolved ($\times 1,000$.)

results tend to confirm the work of Hawes (1909) and Key (1924), in which the close numerical relationship between stippled and polychromatic cells and reticulocytes was definitely established.

The nature of the staining substance is still undetermined, nor has any explanation been offered as to why the different appearances occur. Pappenheim (1907) and Biondi (1908) independently propounded the view that the stainable substance was a dye-precipitate upon the surface of the lipid membrane, but, later, Pappenheim (1919) rather altered this idea, and suggested that the lipid component of the spongioplasm was the reacting substance.

That the substance is not chromatin is beyond doubt. The staining reaction with methylene blue-eosin preparations and with methyl green-pyrimin, and the fact that

none of the conditions is visible by dark-ground illumination or ultra-violet light, are among the arguments against punctate basophilia, polychromasia, and reticulation being nuclear in origin.

Gruner (1913) suggested that the reticular substance was not nuclear but plasmatic in character, because in embryos and young animals its abundance was not associated with the appearances of changes in the nucleus. I have confirmed this observation in cases of Addison's anaemia during normoblastic crises, in von Jaksch's anaemia, and in myeloid leukaemia. In these diseases there does not appear to be any relationship between the younger normoblasts and the older normoblasts and the amount of reticular substance.

The present work is an attempt to elucidate these problems. The fact that haemoglobin gives a characteristic reaction with benzidine and hydrogen peroxide was utilized to the exclusion of all other stains. Blood films were made on 3×1 microscopical slides and allowed to dry in the air before treatment. By altering the quantities of the reagents* it is possible to disturb the apparent homogeneity of the erythrocyte. For the better appreciation of the early effects we will take the final results first. Fig 1 is a photomicrograph of erythrocytes from which the haemoglobin has been more or less completely discharged. Benzidine in alcohol and hydrogen peroxide were used in such strengths that when flooded on to the film a greenish precipitate was immediately produced and floated to the surface, the reaction was allowed to continue for twenty minutes. If the corpuscles in the figure are examined with a hand lens an irregular meshwork is seen, and the spaces between the strands have the appearance of pores. The outline of the cells is irregular, but the mean diameter is increased. The probable sequence of events is that the lipid membrane has been oxidized and dissolved, and a slow fixation has brought into evidence a spongy stroma through the interstices of which the reagents have penetrated. Reaction between the benzidine and hydrogen peroxide and haemoglobin has taken place with solution and escape of the end product. Having seen the end result, all kinds of patterns, depending upon the varying degrees of penetration of the envelope and the amount of haemoglobin

FIG 2.—Erythrocytes showing finely granular punctate basophilia ($\times 1,000$.)

released, would appear possible. This is, in fact, true. Every type of punctate basophilia and reticulation may be duplicated.

Fig 2 is an example of punctate basophilia of the fine type. If the cells are examined with a lens it will be apparent that the reaction has not progressed to the stage of Fig 1. There are areas in which the granules are sharply defined, in others, however, they are blurred in outline, suggesting that the haemoglobin has been reached but different stages of the reaction have taken place. The granules may be fine as in this figure, or coarse as in some of the cells in Fig 4, or they may be irregular in shape and aggregated into small clusters as in Fig 3.

At a further stage the haemoglobin has escaped through

* The reagents are benzidine 0.01 per cent. in 80 per cent. alcohol, and hydrogen peroxide.

the pores and bridged over intervening strands of the stroma Areas have coalesced in an irregular manner and the appearance of reticulation results, as shown in some of the cells in Fig 4

All the forms of reticulation described by Brookfield (1928), from the unfragmented reticulum to the bar form, may be reproduced Fig 5 is an example of the bar form The reticulocytes in Fig 4 suggest that the next stage

results strengthen the belief that the stainable substance is not nuclear in character, but is probably a haemoglobin compound, and that the three basophilic conditions of the erythrocyte are qualitatively the same and vary only in degree The second deduction is that the conditions, when obtained by the usual staining methods, would point to increased permeability or a defect in the lipid envelope of the erythrocyte rather than to youthfulness, although

FIG 3—The clumped form of punctate basophilia showing granules of irregular shape. ($\times 1000$)

FIG 4—Punctate basophilia reticulation and diffuse polychromasia (X) ($\times 1000$)

FIG 5—The bar form of reticulation ($\times 1000$)

must be diffuse polychromasia The cell marked X in Fig 4 illustrates the condition up to a point, but there is a rim of unaffected material around the central stained area This is probably due to the time given for the reaction being too short

Comments

This preliminary note is merely intended to place on record the fact that punctate basophilia, diffuse polychromasia, and reticulation may be produced in any erythrocyte The time is not opportune to enter into the discussion which these results open up, but two deductions may, I think, be made The first that with our previous knowledge of the staining reactions the above

there may be, and probably is, a close relationship between punctate basophilia, diffuse polychromasia and reticulation, and immaturity

I take this opportunity of expressing my thanks to my friend C F Hill for his invaluable assistance with the photomicrographs

BILATERAL OBSTRUCTION OF THE CENTRAL RETINAL ARTERIES

BY

FRANK JULER, M.A., M.B., F.R.C.S.

Surgeon Royal London Ophthalmic Hospital Assistant Ophthalmic Surgeon St Mark's Hospital

My excuse for drawing attention to this subject is that Dr T G Wynne Parry published a report of a similar case in the *British Medical Journal* last February and commented upon the rarity of the condition As a matter of fact, a number of bilateral cases have been reported, a few of simultaneous onset, a larger number with an interval between the incidence of the condition in the two eyes The notes of my patient are as follows

A man aged 50 came to Moorfields on November 20th 1920 having lost the sight of the left eye suddenly two days before The vision was reduced to bare perception of light, white opacity of the retina at the posterior pole of the fundus was already present and the macula showed the typical cherry red spot The arteries were narrow Two weeks later the white opacity of the retina had disappeared The right eye with spherical—2D had 6/9 vision and its retinal arteries showed slight sclerosis Dr Gordon Holmes reported that the blood pressure was high 260/156, and that chronic renal disease was present

On April 5th 1922 he came again having lost the sight of the right eye suddenly five nights before Its vision was reduced to finger-counting at one metre The right disc was atrophic, the arteries were narrow with apparent obliteration in places, and the lumina of the veins were much interrupted There was a cherry red spot at the macula and some whitish specks in that region

* A paper read in the Section of Ophthalmology at the Annual Meeting of the British Medical Association Cardiff 1923

Cause of the Obstruction

The work of Coats and others has made it more than probable that most of the cases occurring in elderly folk are due to endarteritis or thrombosis in the central artery itself and that an embolus is unusual Embolism undoubtedly does occur and is probably the correct explanation of the condition when it is present in young adults who are the subject of mitral stenosis, congenital heart lesions, etc Spasm of arteries, haemorrhage into the nerve sheath and pressure on the nerve itself are other possible, but not so well authenticated causes In a number of the cases occurring in young folk no cause can be detected from a general examination of the subject

Obstruction Occurring during Sleep

Frequently the condition of blocked central artery or vein has been noticed first on waking from sleep, and it has been concluded that in the arterial as in the venous cases this was suggestive of a thrombosis In cases occurring in elderly persons with arterial disease this is likely to be the explanation but it is possible for embolism also to occur during sleep

MacWilliam has recently drawn attention to the not infrequent occurrence of cerebral haemorrhage, anginal attacks and death during sleep, and he has explained this by his experimental observations on the blood pressure in this state He finds that there are two entirely different conditions in question in sleep (1) sound sleep, with lowering of blood pressure, (2) disturbed sleep, dreaming etc which may be attended with remarkable elevations of pressure

In sound sleep lowering of the systolic blood pressure to the extent of 15 to 30 mm at the end of two hours

sleep is found, rising gradually in the later part of the night's rest. In 39 patients with an average systolic blood pressure of 204 Brookes and Carroll found a fall of 44 mm after two hours' sleep. Blum found falls of 15 and 21 mm in normal persons, but falls of 31 and 39 mm in persons with high blood pressures.

Disturbed sleep may cause remarkable elevations of blood pressure, increased heart action, changes in respiration, and various reflex effects. MacWilliam found in one subject an elevation of systolic pressure from 125 to 180, and of diastolic from 75 to 105, an increase much greater than that which was produced by ordinary muscular exercise.

These two types of sleep are of interest to ophthalmologists in that they may both have a bearing on the incidence of arterial block in the retina. In the first, ischaemia may be brought about by the lowering of blood pressure in the presence of endarteritis with or without thrombosis, in the second, a sudden increase may dislodge a clot or a portion of valve vegetation as an embolus.

Is Treatment of any Avail in Recent Cases?

By treatment is meant the administration of amyl nitrite, massage of the globe, and paracentesis. Many cases have been reported as successful. Mr Gordon Mackie, in a letter to this *Journal* (February 18th, 1928), stated that he had seen a definite improvement from treatment. As long ago as 1861 Alfred Græfe reported complete restoration of sight in a bilateral case after iridectomy. Mr Paton tells me of a case in which, after massage of the eye by my father, they saw a retinal artery begin to pulsate again forty-five minutes after a complete block. Mr Harrison Butler has also reported a case of improvement in an embolic case by treatment. Personally, I had had no success until three days ago, when a patient was admitted to hospital under my care two and a half to three hours after a central artery embolism. After amyl nitrite and vigorous massage, the vessels had resumed their normal appearance and the embolus had shifted on to a small branch. The white opacity of the retina had already developed, and it is too early yet to say what improvement of vision, if any, will be effected.

Even if no immediate improvement is noticed it is possible that early intervention may assist in some extension of the visual field, as is perhaps suggested by the following case.

The patient was a young man who had mitral stenosis and a blocked central artery, a small area escaped obstruction, being supplied by a posterior branch from the central artery or by a cilio retinal vessel but there was a macular "cherry" spot surrounded later by white opacity. Three and a half hours after he had discovered the block his vision was finger counting in the temporal part of his field. Treatment made no immediate alteration in his vision but eighteen days later he was able to read 6/36 and three months afterwards he saw 6/24 with the affected eye.

In this case, then, some repair in the function of the retina was undoubted, and this presumably took place in the neighbourhood of the edge of the opacity, which was close to the macula itself. It now seems agreed that the usual refilling of the retinal arteries and the occasional return of vision in that part of the field around the disc are due for the most part to dilatation of capillary anastomoses between the choroidal vessels and the retinal arteries on the disc itself. Now the sooner this anastomosis is opened up the greater should be the area of the retina which is not completely atrophied by the ischaemia, and such a dilatation is likely to be favourably affected by reduction of the intraocular pressure.

Retinal haemorrhages in central artery block are sometimes seen in the neighbourhood of the disc, and are considered as due to the yielding of small capillaries, probably in the opening up of anastomoses. They might be considered as a contraindication to paracentesis. I feel, therefore, that it is right to give treatment to any recent case, but that paracentesis should be avoided if haemorrhages are present.

How soon does the White Opacity of the Retina Appear?

De Schweinitz reports that he has seen the white opacity develop as he watched a patient with the ophthalmoscope ten minutes after sudden loss of vision. Of recent cases

under my care opacity of the retina was developed in one patient when first examined two and a half hours after the onset of blindness, in another three and a half to ten hours after the onset, becoming fully developed during the following twenty-four hours, in a third (Alford) it was well marked in nine to fifteen hours.

Visibility of Embolus in a Branch Block

We would expect an embolus to be visible at the bifurcation from which the occluded branch comes. I have only seen three cases in which there was anything visible at this point, and in two of these the mass was apparently external to the vessel. In one it disappeared, in the other it persisted.

The first of these patients was a lad of 21 years, who was passed sound in heart and mind by Dr Gordon Holmes. About twenty-seven hours after the incidence of a block in the inferior temporal branch I noted that "on the disc a small bit of this artery appears collapsed narrow like a thread, at the disc margin and beyond the calibre is normal again." That afternoon Hamblin's artist made a drawing of the fundus which shows a white collar round the vessel at the site of the previous narrowing. This was confirmed by Mr Doyne three days later, on December 6th, but by December 13th Doyne found that the mass had disappeared. On December 31st I too, found no white mass on the vessel, nor was any local constriction or abnormality apparent.

My other similar case was that of a lady aged 47, who had always been an invalid owing to a congenital heart lesion. Some six months previously she had lost the lower field of the right eye suddenly. The ophthalmoscope showed a discrete ovoid bright mass seated on the origin of the superior temporal branch which was well within the disc margin. It covered this vessel being considerably wider than it. Otherwise the vessels looked healthy. I saw this lady again fifteen months later and the mass was unaltered in appearance.

I surmise that in these two cases there was some local reaction in the perivascular sheath round the embolus, possibly associated with a toxic effect of the latter, and that in the one case it was small enough to be absorbed, while in the other it has become organized into a mass of fibrous tissue or cholesterol.

Recently a woman of 38 was admitted to hospital with embolism of the central artery. The appearances of the arteries on the disc were not as if they were collapsed but as if they were filled with a colourless material for a short distance from the centre of the disc the normal coloration being regained just within the disc margins, and the calibre being the same throughout. After treatment the vessels appeared normal again, but further search showed a colourless segment at a bifurcation along the inferior temporal branch. Later in the day this again had moved on and another similar segment was found still more peripherally.

In another case, under Mr Paton, a drawing showed a white mass over the site of an embolus, this perhaps comes in a somewhat different category, as there was a good deal of haemorrhage about it, and it occurred in a patient who was the subject of a malignant endocarditis.

Hay has reported a case with "a spindle shaped greyish-white swelling distending the lumen of the temporal branch at the fork of the inferior retinal artery." Knapp says that the embolus can be frequently observed, and appears like a bright round or angular body.

Pulsation of Vessels beyond the Block

As is well known, it is usual for the vessels peripheral to the block to fill up after the initial collapse, and it is interesting to note in this stage how much finger pressure on the globe is necessary to produce visible pulsation in the arteries. It has been noted by several observers that pulsation beyond the block in central artery obstruction is not obtainable, collapse of the vessel may be obtained, but not pulsation. By some this has been given as a diagnostic sign of some importance in doubtful cases, but it is certainly not invariable, for I have seen pulsation easily elicited in a congenital heart case with embolism of the main central artery.

I have noted, however, in my two cases of branch block above quoted that I was unable to produce pulsation in the branch beyond the block, using an amount of pressure considerably beyond that which produced pulsation in the unaffected branches. It is to be noted that in both of these cases the block was situated on the disc itself and the distal parts of the vessel were probably filled by dilatation of capillary anastomoses from the posterior ciliary vessels near the margin of the disc. In that case no pulse transmission would occur into the vessel, and the flow of blood therein would be very slow.

In the recent case which I have just quoted, in which the embolus moved on into a smaller branch, finger pulsation was afterwards easily elicited in the arteries on the disc

MYOMECTOMY DURING PREGNANCY *

BY

R VAUDESCAL, M D,

Professeur Agrégé à la Faculté de Médecine de Paris

In this very short review, for which are taken as a basis cases observed in the Clinique d'Obstétrique et de Gynécologie de la Faculté de Médecine de Paris (Professor Brindeau) during the last four years, I will confine my observations to the indications and operative technique of myomectomy during pregnancy.

Primarily, let it be understood that judgement and common sense are required in the selection of each case for myomectomy during a pregnancy. As regards the indications for myomectomy in cases complicated by the presence of a fibroid or a myoma, it is only very exceptionally that operation during pregnancy is the correct procedure because usually these tumours, while they may give rise to difficulty during the actual labour, seldom cause trouble during the pregnancy. Moreover, if it is remembered that the scar left by the operation may be the site of a rupture of the uterus during labour (and such cases are on record) it will be agreed that this procedure is to be avoided if at all possible. However, we are bound to admit that myomectomy is indicated in certain cases, these being as follows:

1 When the fibroid is large and is diagnosed early during the pregnancy, before the third month, and when the swelling of the tumour is easily distinguishable from that of the uterus. By performing myomectomy at this time all possibility of complications is avoided during both the pregnancy and the labour.

2 At any time during the pregnancy when unmistakable signs of necrobiosis of the fibroid appear. Necrobiosis is indicated by the tumour becoming acutely painful and frequently softer in consistency. This is often preceded by hypertrophy of the fibroid, and at the same time there are signs of peritoneal reaction, such as vomiting, abdominal rigidity, and a weak pulse.

3 When, owing to the presence of a fibroid there is an axial torsion of the uterus or a partial retroversion causing a kink in its longitudinal axis and threatening to bring about the termination of the pregnancy.

4 When there is torsion of the pedicle of the tumour, the symptoms of this occurrence being severe and lasting pain accompanied by the symptoms of peritoneal reaction mentioned above.

5 When the fibroid causes pressure on the neighboring organs the chief of these being the bowel (occlusion), the ureter (hydronephrosis, pyelonephritis, or anuria), the urethra (retention of urine), and the veins in the pelvis, causing oedema or thrombo-phlebitis.

With the exception of the foregoing there are no indications to justify a myomectomy during a pregnancy, although it is admitted that such an operation may be successful in other cases.

As for the operative technique, the main points for consideration are as follows:

1 General anaesthesia is preferable to spinal anaesthesia, the reason being that in the latter the contractions of the womb are not suppressed, and are even exaggerated.

2 The tumour should be decapsulated by a single incision running over its summit, and not removed by a circular incision around its base. This allows of easier decapsulation of the tumour, and also of easier closing of the peritoneum afterwards.

3 All bleeding must be carefully stopped. The best method to employ is to understitch the bleeding point with thick catgut, this must be tied loosely to avoid cutting through the tissue.

4 In cases where the fibroid is between the layers of the broad ligament an attempt should be made to approach the tumour by the transligamentous route, incising the anterior or the posterior leaf. Care must be taken to avoid the uterine vessels and the ureter while doing this.

5 No drainage should be employed.

6 Morphine should be given in large doses during the three days following operation. I give 1/6 grain every six hours.

Following these principles the following results have been obtained during a period of six years (1920-26):

Total myomectomies performed during pregnancy	52
Number of myomectomies followed by abortion	4
Number of myomectomies followed by premature labour	4
Number of cases going to full term	41
Maternal mortality	1
Cases not seen again after leaving hospital	2
Infantile mortality including abortions	7
Average maternal mortality	1.9%
Average infantile mortality	13%

Since January 1st 1924 we have operated on 21 women not only during pregnancy but also during labour and the puerperium. In 8 of these patients we were able to perform a myomectomy 3 before term (1 after abortion) 2 after full term and 3 during the puerperium. In 7 cases a living child was obtained. Hysterectomy was performed in 13 cases as follows: 1 vaginal after abortion 6 without Caesarean section (1 two months pregnant, 1 three months pregnant 1 six months pregnant and 3 during the puerperium) 6 after Caesarean section. In 9 cases living children were obtained.

These statistics show that out of 21 cases we were only obliged to operate five times during pregnancy, twice after abortion, eight times at full term, and six times during the puerperium. In other words, in 38 per cent of the cases myomectomy was employed, and in 62 per cent of the cases we were obliged to perform hysterectomy.

This it should be borne in mind that if operation is undertaken during pregnancy it is necessary in 62 per cent of cases to perform hysterectomy. Operative intervention during pregnancy should, therefore, be postponed as long as possible in order to obtain a living child.

ABDOMINAL ANEURYSM DEATH SEVENTEEN YEARS AND SEVEN MONTHS AFTER OPERATION

At the Annual Meeting of the British Medical Association held in Birmingham in 1911 I reported a case of abdominal aneurysm which had been treated the previous year by the introduction of a Colt's cage of 150 inches of wire. At the time of operation there was a large sacular aneurysm in the region of the coeliac axis. The patient had been under careful medical treatment for eight months previously. A few days after operation the aneurysm commenced to harden. Eleven months later an abdominal aneurysm could still be recognized from continued pulsations and a persistent murmur below the tumour, but all pain and discomfort had disappeared and he resumed work without inconvenience. Later still the murmur disappeared, as did all trace of expansile pulsation. To the end a hard mass could be felt with transmitted pulsations from the aorta. There was a history of syphilis and for the last few years the man showed signs and symptoms of locomotor ataxia in a very chronic form.

On March 29th last the assistant medical officer of Guinness's brewery was called to see him. He complained of pain in the right lumbar region and lower abdomen. Examination revealed nothing of significance. The site of the aneurysm (in the upper left quadrant) was not

* A paper read in the Section of Obstetrics and Gynaecology at the Annual Meeting of the British Medical Association at Cardiff 1928.

larger than previously, and there was no increased pulsation. He had been constipated for some days. There was no abnormality in pulse or temperature. On March 30th his condition was much the same. That night the bowels moved well and he got immediate relief of pain. The following morning (March 31st) he sent a message to the doctor that he felt quite well. Later in the day he sat up in bed and fell back dead. Unfortunately the circumstances were such that no *post-mortem* examination was possible.

Many patients have been cured by the introduction of air into the sac of an aneurysm, but I believe that in no other case on record has the patient survived for so long a time. The man whose case is here recorded was 38 years of age when the operation was performed on August 30th, 1910.

CHRONIC NASAL SINUSITIS WITH MENTAL SYMPTOMS

IN view of the call for publication of instances of insanity associated with chronic nasal suppuration two such cases are now reported. It must not be taken, however, that they are cases of toxic psychosis resulting from the sinusitis, for such a conclusion to be drawn not only would a large number of cases of the association of sinusitis with mental symptoms need to be recorded, but the sequence of the insanity on the sinusitis and the sequence of its cure on the cure of the sinusitis must also be shown. In each of the following cases the sinusitis preceded the mental symptoms. The first patient had a right-sided pansinusitis, all the cavities were drained, but the patient died some years later in an asylum. The second had a bilateral pansinusitis, all the cavities have been dealt with and are practically well, but the patient is in an asylum. It must be noted, however, that the cure of the sinusitis is comparatively recent.

CASE I

A riveter aged 46 consulted me in October 1920, on account of asthma which had existed ten years and had kept him from work for the previous year. While the asthma improved for some months after nasal and other treatment, and, as frequently happens, after his several admissions to hospital it always recurred sooner or later, and he seems to have died from its effects on his right heart. The patient had some emphysema, a normal blood pressure and a distinct eosinophilia varying between 8 and 11 per cent—clear indication in my opinion of acidotic tendency, that is of a toxicosis. The granules of the polymorphonuclear cells also took the eosin unusually well.

In November and December 1920, operations were performed on the septum and middle turbinates, and for two months his asthma improved. In January 1921, he complained of right frontal pain. Proof puncture of right antrum was negative, since there was pressure from a large bony cyst which formed the bulk of the ethmoid and reached to the sphenoid; this cyst was removed and the sphenoid was opened but no pus was found (March 1921). The pain above the right eye persisted and some small tags of turbinal root-plate close to the nasal roof were removed three weeks later. During this operation the cribriform plate was accidentally opened and cerebro-spinal fluid escaped. The part was painted with iodine, no plug was inserted, first argyrol and later chloramine-T were regularly instilled, hexamine was given by the mouth and the patient was kept sitting for three days and nights. He recovered without ill effect. In April it was noted that he remained free from asthma and had little pain. In May, however, he showed distinct evidence of frontal sinusitis yet had little pain and could walk for miles, but in November his doctor sent him back to Glasgow Royal Infirmary on account of severe pain above the right eye. The ethmoid and sphenoid cavities were further opened; a "Howarth" operation was performed on the frontal bone and a "Denker" on the antrum. Pus and pulpy membrane were found the frontal mucosa was pulpy throughout. During this residence in hospital he had delusions of suspicion regarding the other patients. In 1922 there was little pus in the nose, he received a double course of peptone injections without benefit to the asthma. In October 1923 and January 1924 he was still in Stobhill Hospital because of asthma. He had delusions of persecution and in 1925 he was admitted to Bothwell Asylum. Dr Buchanan reports that the patient had suspicious delusions, aural and visual hallucinations, severe asthma, chronic bronchitis and dilated heart, no signs of nasal suppuration were noted. Dropsy supervened and death followed in February, 1926. Permission for necropsy was refused.

CASE II

A man aged 35, was admitted to Stobhill Hospital in November, 1924 complaining of dizziness and pain in occiput and root of nose, also of a feeling of depression since the war. (His left antrum had been opened in the Glasgow Royal Infirmary.) There was a pansinusitis, all the cavities were opened intranasally, and the

patient was discharged in March 1925. Because of mental depression he was thereafter admitted to Woodilee Asylum, and again transferred to Stobhill on account of pus coming chiefly from the frontal sinuses. The antral openings were enlarged, the ethmoid was dealt with, and a "Howarth" operation was performed on the right frontal sinus. Pus had practically disappeared from the nose in January, 1928, when, as the patient continued to be depressed and emotional, he was sent back to the asylum.

No doubt the nasal condition in each patient aggravated the mental symptoms, and that is probably the most that can be said. The first was distinctly neurotic before the onset of sinusitis, the second gave the impression of being a "hospital bird." It is perhaps worthy of note that in both cases the frontal sinus was involved.

It is greatly to be desired that the mental symptoms associated with chronic sinusitis, and those associated with frontal lobe abscess, be particularly observed with a view to possible differentiation. In other words, what are the mental symptoms of "toxic psychosis" as distinguished from those of frontal lobe abscess?

Throat Glasgow Parish Council

ONYCHIA TREATED WITH VACCINE

THE following account of the successful treatment of a patient with onychia by injections of a sensitized vaccine seems worthy of record.

The patient, a man aged 43, gave a history of having had pneumonia influenza in 1918. He complained of pain round the base of the nail of the left ring finger, and of slight discharge of pus. This condition had been present for four weeks. Examination showed the presence of inflammation round the base of the nail, associated with thin purulent discharge. The diagnosis was onychia due to coccal infection.

Treatment. For three weeks boracic fomentations were tried without any benefit. As it was very important to get a speedy cure, the patient being a medical practitioner, the advisability of removing the nail was considered. Before resorting to this measure the injection of a sensitized vaccine of 1,000 million *Staphylococcus aureus*, 1,000 million *Staphylococcus albus* and 1,000 million streptococci per cubic centimetre was begun. The dose given was 3 minims. The injection was given subcutaneously in the upper arm. Some temporary improvement followed this procedure. At the end of another two weeks the onychia had relapsed and was now as bad as ever. A second injection was then given, subcutaneously close to the base of the nail. The dose was 4 minims. Within a few hours a violent reaction occurred. This persisted for about thirty-six hours and then gradually subsided. At the end of ninety-six hours from the time of injection practically all pain had left the finger and there was no purulent discharge. On the sixth day the finger was normal, and has remained so since that time.

Considering the chronic nature of many cases of onychia and the brilliant result of the treatment adopted in this case, I thought the matter might be of interest to other practitioners.

FATAL CASE OF ACCIDENTAL POISONING BY BENZOL VAPOUR

THESE cases are so rare that I thought it would be interesting to give the particulars of a fatality which recently came under my notice. Looking through my forensic literature I was only able to find one recorded case (Dixon Mann's *Forensic Medicine*), and in that the patient, unlike the present one, recovered.

A man, aged 26, skilled in his work, descended into a benzol mixture spirit tank to clean it out, taking some swabs with him. The capacity of the tank was 2,000 gallons and it was thought that water had gained access to the spirit. It was entered by a circular manhole, with a diameter of 16 inches. A gas mask was worn, with a wide bore flexible air ingress tube attached, which was of considerable length. This tube was held by an assistant with the inlet near an open window. The man concerned was usually fitted with a life-line to enable him to give signals to his mate above. But after working so equipped all the morning he discarded the line after his dinner and descended without it.

During the morning he kept coming out of the tank frequently for a brief period according to custom, but he never emerged again after his 2 o'clock descent. The attendant upon the air pipe did not note cessation of its movements; he said till after 3 o'clock. An alarm was immediately raised and the fire brigade sent for with pulmotor and all life-saving apparatus. A fireman descended wearing a life-line and having a wet cloth over his mouth and nostrils. The cleaner was seen prostrate at one end of the tank with difficulty he was attached to the line and brought with his would-be rescuer into the air. The latter was

feeling the effects of the gas a good deal. The man in the mask was dead.

On the coroner's order I made a *post mortem* examination twenty-four hours afterwards. Externally nothing abnormal was observed beyond a slight yellowness of the facial death pallor. Some saliva had run from the mouth into the facepieces of the mask. Rigor mortis was present. Internally, beyond old-standing pleural adhesions, the body was healthy, but emitted a strong smell of benzol. The blood was fluid. No clots were found anywhere, not even in the heart, and both ventricles were firmly contracted. In bulk the blood had an unusually dark appearance but in film it was almost cherry red. It left a light coloration upon the smeared costal cartilages and upon the tissues with which it came into contact. The contrast between this body when fully opened and another one in a similar condition on an adjoining table was marked. The smeared appeared to act as a stain, and could not be clearly washed away. The spectroscopic appearances were those of oxyhaemoglobin, and reduction was easily effected by ammonium sulphide.

The meninges and brain showed marked congestion. The brain substance on section was studded with minute red points throughout. The only other finding was pulmonary oedema. The air passages contained thick gelatinous mucus. The lungs were very dark in colour and exuded a frothy liquid on section or pressure. The stomach contained a meal of meat and vegetables, quite undigested. The mucosa was normal and the same may be said of the bowel throughout. The bladder contained clear urine.

I deal with the *post-mortem* findings only, and refrain from offering any opinion as to how the benzol vapour found an entrance to the respiratory passages of this unfortunate man.

CLINICAL AND SCIENTIFIC PROCEEDINGS

LANCASHIRE AND CHESHIRE BRANCH

Treatment of Auricular Fibrillation

A SCIENCE meeting of the Lancashire and Cheshire Branch was held at Bury Infirmary on October 18th, with the president, Dr J H MARSH, in the chair. Dr J CRICHTON BRAMWELL read a paper on the treatment of auricular fibrillation.

Dr Crichton Bramwell commented on the great importance of auricular fibrillation in view of the large number of cases of heart failure attributable to this abnormal rhythm. Twenty years ago Lewis had shown that delirium cordis in man was identical with fibrillation in animals, and that the appearance of heart failure with congestion in these cases was largely due to the excessive ventricular rate. By slowing the ventricle digitalis reduced the work of the heart, and at the same time, by prolonging diastole, it improved the venous filling and increased the coronary blood flow. The excessive dose method, introduced by Eggleston, might be safely used in urgent cases, provided that the patient had not previously been taking digitalis, and that an interval of six hours was allowed to elapse between successive doses. When the symptoms were less urgent 20 minims of the tincture three times a day would usually produce the desired result within a week. Quinidine actually stopped fibrillation in over 50 per cent of the cases treated. Many, however, subsequently relapsed, and if there was much myocardial damage the patient derived little or no benefit from the restoration of normal rhythm. Of twenty-eight rheumatic and fibrotic cases treated with quinidine which Dr Bramwell had followed up, two were still normal five years after their initial course of quinidine, and seven others had remained normal for two years or more. When fibrillation persisted in cases of hyperthyroidism in which the thyroid condition had been successfully treated, quinidine was valuable, but the rheumatic and fibrotic cases showed a greater tendency to relapse. The danger of embolism was another drawback to quinidine therapy.

Radiography of the Gall-bladder

Dr A RICHARDSON, in a paper entitled "Radiography of the gall bladder," recalled the fact that prior to the introduction of the dye method radiological evidence was confined to cases in which gall stones contained sufficient calcium to cast a shadow on the film. X-ray departments were now expected to report on the normal or pathological

condition of the gall-bladder. The oral method of administration of the dye had been proved to be simple, reliable, and safe. Dr Richardson enumerated and discussed five contraindications to its use: obstruction of the common duct, the presence of extensive hepatic destruction, hypertension, cardiac disease, and hyperthyroidism. He stated that the shadow of the gall-bladder appeared between the fifth and the eighth hour, the maximum concentration occurring between the eighth and twenty-fourth hour. The shadow faded completely between the twenty-fourth and forty-eighth hour after administration. The method demonstrated not only the presence or absence of stones, but also the occurrence of pathological conditions of the gall-bladder, even in very early stages of disease. The paper was illustrated by a series of prints.

Plastic Surgery of the Eyelids

Dr J RATCLIFFE showed a case illustrating plastic surgery of the eyelids. He explained that this case was of some interest from three points of view: (1) it was purely a "civil practice case", (2) both lids of the same eye were involved, and (3) the patient was a female. Dr Ratcliffe remarked that during the war most practitioners had encountered many cases which lent themselves to facial plastic surgery, but such cases were rare in civil practice. They seldom met with cases where plastic operations had been performed on both the upper and lower lids of the same eye with any measure of success. Since the patient was a female considerable care was necessary in respect of the resultant cosmetic effect produced by the operation.

On New Year's Eve 1926 the patient was sitting in front of the fire when she was seized with a fainting attack. She fell forward on to the fire and severely burned the left side of her face. This was treated by her own doctor until the early part of March 1927 when the patient was sent to Dr Ratcliffe. He found marked scarring of keloid appearance of the left side of the patient's face, especially in the region of the eyelids. This caused very marked retraction and eversion of both the upper and lower lids making it impossible for them to be brought into contact. As a result of this the left eye was beginning to show definite signs of ulcerative keratitis and the patient's personal appearance was, to say the least, very repulsive, so much so that she was suffering more from the mental worry of her appearance than from the eye condition. It was obvious that something had to be done, first, to save the left eye and secondly for the patient's personal appearance. On March 21st Dr Ratcliffe decided to operate on the lower lid. He resected as much as possible of the scar tissue involving this lid taking care to leave the lid margin with the eyelashes *in situ* and the lacrimal duct. This having been done he chose a suitable site on the left cheek and made an incision in the form of a tennis racket, leaving the base of the handle attached. This flap of skin he dissected off and swung into the position of the lower lid suturing it into the adjoining skin. The raw area on the cheek was about the size of a five-shilling piece. This he filled in by Thiersch skin grafts taken from the inner side of the patient's left thigh. On June 6th he carried out a similar procedure on the upper lid. Both the above operations were performed under rectal anaesthesia, which in his experience was very satisfactory for such cases.

Dr Ratcliffe added that (1) the patient could now bring the lids together, (2) the eye presented a normal appearance, (3) the patient's face was now far removed from being repulsive.

Reports of Societies.

HYPOCHONDRIA

At a meeting of the Section of Medicine of the Royal Society of Medicine on October 23rd, with Dr ROBERT HUTCHISON in the chair, Dr R D GILLESPIE in opening a discussion on hypochondria explained that the work on which his paper was founded had been done as Pilsent-Darwin student of Cambridge University.

Dr Gillespie remarked that "hypochondria" as a medical term had undergone many vicissitudes. Something of its history was revealed in the variety of conditions for which it was taken as a sufficient description at the present day. It had been, and was still, identified with hysteria, melancholia, and neurasthenia. From hysteria, however, he held that it differed quite clearly. The hypochondriac had the conviction that he was suffering from some malady, and rejected reassurance if he asked

for sympathy it was something which did not involve quite that affectionate dependence on the physician which was manifested by the hysterical patient, who was ready to be convinced that what he, or more usually she, suffered from was a delusion. Some of the older psychiatrists distinguished a "hypochondria cum materia" and a "hypochondria sine materia," according as gross organic disease was present or absent. There had been a long standing dispute whether a syndrome (or in psychiatric terminology, a reaction-type) to be called hypochondria existed *per se*, or whether hypochondriacal symptoms occurred only as part of a larger symptom complex. Dr Gillespie's contention was that such a syndrome could usefully be distinguished. Its principal characteristics were a persistent pre-occupation with the bodily health, in excess of what would be justified by any physical disturbance that was present, also an emotional attitude best described as "interest with conviction." Anxiety, in the sense of fearful apprehension of disease, was absent, simply because the idea that disease was present was settled in the patient's mind—it was not apprehended by him. The merely anxious patient feared, but he did not believe, that he suffered from a malady, for the hypochondriac the fancied ailment was real. Other characteristics were inaccessibility to psychotherapy, and the running of a chronic course without intellectual or emotional deterioration. He quoted fourteen cases, of which three were fairly typical examples of hypochondria as above defined. Of the remainder, several illustrated conditions resembling hypochondria in the strict sense, but exhibited various clinical differences, including accessibility to therapy, and a favourable outcome; they were quoted to support a hypothesis of the psychopathological basis of some cases of true hypochondria, and of hypochondriacal complaints in other syndromes. Prognosis in hypochondria depended on the relative importance of exogenous and endogenous factors. The more the condition could be regarded as a reaction to external circumstances—including for this purpose organic disease—the more favourable, on the whole, was the prognosis, the more it was the outgrowth of the patient's personality the more doubtful must be the outlook. Young hypochondriacs were more curable than old. The treatment must include that of any organic disease which might be present, without too much emphasis upon it, also psychotherapeutic treatment of a very ordinary kind (these persons did not lend themselves to much psychological investigation), and the usual common-sense measures with regard to occupation and ordering of habits.

Dr R S ALLISON said that the view that hypochondria might be regarded as a definite entity, and not merely as a variety of some other form of disease, had an attraction for those in general medicine, who were frequently confronted with patients showing no other evidence of mental disorder than this abnormal concentration on the bodily state. He thought that Dr Gillespie's phrase "interest with conviction" was a good description of the emotional attitude of these people. It was not usual for the hypochondriac to complain of definite pain at a certain point—if there were such pain it would raise the suspicion of organic disease—but rather a sense of uneasiness. In dealing with hypochondriacs who had previously had abdominal operations it would often be discovered on careful inquiry that the pain or discomfort complained of was essentially similar to that experienced before the operation. Treatment was undertaken with the faint hope of removing the false impression in the mind, checking harmful tendencies (such as the abuse of aperients, frequent intestinal douching, and the craving for abdominal operations) following such impressions, and the diminution of the sensations complained of in so far as these had any ground in reality.

Dr W R REYNELL considered that Dr Gillespie had established his thesis that there was a definite clinical entity such as he had depicted, but as described and delimited by him it was a rare condition. The condition was persistent and that would exclude manic-depressives and similar people in whom this state of mind was periodic. Dr Gillespie had stated that the preoccupation was in excess of what would be justified by any physical dis-

turbance that might be present, but this was very hard to assess in a case, for example, of marked visceroptosis. The conviction of the hypochondriac really amounted to a delusion, and the cases as defined by Dr Gillespie were inaccessible to psychotherapy, but on a broader definition of hypochondria, including cases which Dr Gillespie would not admit as the prime condition, psychotherapy was far from being futile. He would rather define hypochondria for practical purposes as a morbid preoccupation with health, in the absence of demonstrable organic disease. He believed that very often there was a predisposition to hypochondria in childhood, and that this could be averted. The child of low vitality, low blood pressure, with toxic debility—the atonic type of child—was markedly disposed to hypochondria in later life. He thought that if a wider definition of hypochondria were accepted, treatment by a rational psychotherapy was very satisfactory, the best "drug" in these cases was the spoken word, but it must be spoken in the right way.

Dr T A ROSS said that it was very important to establish which kind of psychoneurosis was likely to benefit from treatment and which was not. The amount of time which it was necessary to spend on any one case made it necessary to endeavour to exclude at the beginning all those cases which were not likely to derive benefit. He believed that there was a class of case, mostly consisting of old men, sometimes old women, which was absolutely inaccessible to treatment. This did not imply that nothing could be done for them, the best thing that the honest doctor could do for them was to prevent them from falling into the hands of quacks. He was doubtful whether Dr Gillespie had made out his case that there was no great difference between hypochondria and hysteria, and Dr Ross differed also with regard to the anxiety patient who, according to Dr Gillespie, only apprehended disease and knew that he had not got it. These patients might be convinced that they had no disease, but they felt that there was "something wrong" with them, they were inclined to suppose that if there was no macroscopic pathology there must be a microscopic one. Dr Gillespie had also said that the hypochondriac had not the "affectionate dependence" on the physician which was shown by the hysteric, but this might well be explained by the fact that the vast majority of hypochondriacs were elderly men, naturally self-contained and obstinate, and in any case less likely to show "affectionate dependence" than the young.

Dr C P SYMONDS agreed that Dr Gillespie had described a very definite clinical picture. Hypochondriacal symptoms appeared in a variety of mental disorders, perhaps most commonly in manic-depressive psychoses, and he believed that this type of hypochondria was missed more often by the general practitioner than he ought to be. These people eventually found their way to the neurologist under the provisional description of neurasthenia, but often by that time they had suffered unnecessary investigations, including perhaps the exploration of the abdomen. A point most often overlooked in simple clinical investigation was the family history. He had found again and again that no definite inquiry had been made into a family history of mental and nervous breakdown. In anxiety conditions hypochondriacal symptoms were associated for the most part with fear, the settled conviction found in other cases was replaced by an agonized expectancy. He quite agreed with Dr Ross that it was possible to find in one and the same patient a fear as to oncoming disease and a settled conviction that disease was present. The true hypochondria, according to the clinical picture which Dr Gillespie had isolated, was somewhat rare. He might appear to be more common to the general practitioner, because a patient with that type of hypochondria probably consulted a new doctor every month. The speaker described one interesting case of a hypochondriac upon whom a number of operations had been performed, but whose obsession remained, until his wife, to whom he was devoted, fell ill, and required an urgent operation. After this the hypochondriac became, if not entirely well, a changed man, and the wife was accustomed to say that the operation upon herself had

done for her husband what his own operations had been unable to effect!

Dr I PARKES WEAVER was astonished that so many different classes of cases should have been referred to as having hypochondriacal symptoms. He would have thought that the term "hypochondriac" ought almost to be restricted to the typical case suggested by Dr Gillespie. A Greek philosopher said with regard to the hedonists, "Call no man happy until he is dead," and perhaps one should say that no man ought to be called a hypochondriac until it could be placed beyond dispute that there was no physical basis for his preoccupation. He described a case of the kind to which, he thought, the term should be limited, and added that much care should be taken before admitting any other kind into the same category—certainly not those cases of women, mostly young or middle-aged, who had had a number of abdominal operations.

Dr JOHN CURSWELL had hoped that the term "hypochondria" would disappear entirely, or be used only for the involuntarily case, which was so strikingly dramatic, sometimes tragic because of its association with suicide. One could not fail to realize how frequently symptoms of a hypochondriacal nature were found in the early stages of mental disorders. He had seen them occur in the early stages of general paralysis, and indeed over the whole range of mental disorders one found a short preliminary period when the patient was preoccupied with his own bodily feelings of a depressing character. Even before the plunge into delirium the patient in delirium tremens was restless and anxious referring to abdominal and other sensations of a hypochondriacal character. He had never seen a person suffering from hypochondriacal symptoms associated with some disturbance of the internal organs, and getting the better of his physical and of his mental condition, who had not taken in hand his own treatment and defied his doctors.

Dr ROBERT HUTCHISON, closing the discussion, said that he had felt himself to some extent in a foreign country. He was not very familiar with the terminology of modern psychiatrists, and a good deal of what had been said was frankly to him as a general physician unintelligible. He saw the hypochondriac as a perfectly ordinary, harmless person usually an elderly gentleman retired from business, collecting symptoms as other people collected postage stamps, and making his health his hobby. It was true that most of the "specimens" he so collected were fakes, but every now and then in his search for symptoms the hypochondriac stumbled upon a genuine example. He believed this kind of person to be entirely incurable. It would be unkind to cure him, for that would be to deprive him of his one interest in life. What might well be discussed was "the psychology of the hobby-horse," the study of the psychology of those people who developed a mania for one particular thing. Just as the hypochondriac collected abdominal or cerebral symptoms so another man would collect porcelain of the Ming dynasty or old Chelsea. He believed that psychologically there was something very similar in both kinds of people. It had been said that the hypochondriac was egocentric, this was not always so, for there was such a thing as vicarious hypochondria, as, for example, the parents who were desperately fussy over their children and imagined them the victims of all kinds of ailments, or the unmarried daughter living with an old parent who imagined him or her to be suffering from all manner of complaints. It was Bishop Butler who asked whether a whole nation could go insane, but it really seemed possible for a whole race to become hypochondriacal. There was an example in the Jews. Thanks to Moses, who laid down a sanitary code, the Jews had devoted far too much attention to the study of personal health and illness. Whether the genuine hypochondriac could be spoken of as a hysteric he would not like to say. The hysterical person seemed to have a more definite purpose to serve or an advantage to gain, whereas the hypochondriac went about collecting symptoms in a purposeless kind of way deriving no benefit at all, except the interest in life afforded by having something to do. Hypochondria had a very small literature, and therefore the discussion had been all the more useful.

Rebuelus.

DIFFERENTIAL DIAGNOSIS

THE appearance of a fourth edition of the *Index of Differential Diagnosis of Main Symptoms*,¹ edited by Dr HERBERT FRENCH, should be received with acclamation, as this monumental work has been out of print for five years. The book has been thoroughly revised and several new articles have been added, but the general principles remain the same as in previous editions. The illustrations have been considerably augmented in number, and a new feature is the incorporation of the coloured figures in the text in place of the series of plates which adorned the earlier editions, thus much facilitating ease of reference. Of those who contributed articles to previous editions death has claimed Sir Malcolm Morris, Sir Frederick Taylor, and Dr F. J. Smith, while several other names no longer appear in the list of collaborators. On the other hand, the names of Dr S. Ernest Dore, Mr W. M. Mollison, and Dr John H. Ryffel appear as contributors for the first time. In this connexion we cannot refrain from noting that some of the articles seem to have changed their authorship without in fact changing so much as a single word of their text. For example, in the third edition the article on abnormalities of gait appeared over the name of the late Dr F. J. Smith, whereas in the fourth edition precisely the same text bears a different signature. In the third edition the article upon insomnia was attributed to Dr A. J. Jex-Blake, yet although he is a contributor to the new edition, the same article, word for word, appears over the name of another contributor. The solution of such puzzles is, however, a comparatively minor point, the essential thing being the quality of the articles, and these we can say without hesitation reach the highest standard of excellence, and must rank among the best of their kind in the English language.

In a work of this nature the index is perhaps the most important section of the whole book. An inadequate or a loosely constructed index could very easily destroy the whole value of the volume as a useful work of reference. In this respect Dr French has once again excelled, and it is doubtful whether a more complete or conveniently arranged list of complex cross references has ever been added to a medical encyclopaedia, it makes consultation a delight instead of an occasion for profanity, as is only too often the case.

The book has been increased by more than 200 pages, and has now just about reached the limit where compression into a single volume is possible. The illustrations throughout, both plain and coloured, have been singularly well chosen, and the reproduction, especially of the radiograms, has been superlatively executed. Both authors and publishers deserve great praise for producing a volume which in substance brings the highest credit to British medicine and in format holds its own with the most lavish of transatlantic productions. As translations into French and Spanish of the earlier editions have already been made the book is assured of a world-wide success.

GLYCOSURIA

Dr MALMIROS directs his *Study of Glycosuria*² to the particular subject of glycosuria discovered by routine examination of the urine without any subjective symptoms in the patients. This is a point of special interest to medical examiners for life insurance and to general practitioners. As the author says, cases of glycosuria are found accidentally "in which the prognosis was apparently favourable while the diagnosis appeared uncertain" (It should be noted in parenthesis that this Swedish physician writes clear and fluent English.) The monograph represents a big piece of work thoroughly and scientifically carried out. Two main problems are attacked the significance of

¹ *An Index of Differential Diagnosis of Main Symptoms*. Edited by Herbert French. C.B.E. M.D. Oxon. F.R.C.P. Lond. Fourth edition. Bristol: J. Wright and Sons Ltd. London: Simpkin Marshall Ltd. 1928. (64 x 10½) pp. xi + 1171. 701 figures. 63s. net.)

² *A Study of Glycosuria with Special Reference to the Interpretation of the Incidental Finding of a Positive Reduction Test*. By Hagvin Malmiros. Acta Medica Scandinavica. Supplementum xxvii. Lund: Berling & 1928. (Med. 8vo pp. 365. 6 plates.)

so-called "alimentary glycosuria" in apparently healthy individuals, and the factors which affect the blood sugar curve in glucose tolerance tests. Dr. Malmros lays great stress on a point which has hitherto not received much attention—namely, that a low carbohydrate intake immediately preceding a glucose tolerance test may give rise to an abnormal hyperglycaemia (quoting Hofmeister's observation made in 1880 that glycosuria, after ingestion of carbohydrates, is more readily produced in starved animals). Therefore he lays down the rule that blood sugar analyses must be made before any dietetic treatment is commenced, or that if carbohydrate restriction has been started the patient should be given ordinary carbohydrate food before any blood sugar tests are undertaken.

Contrary to general opinion, Dr. Malmros holds that emotion, fear, and nervousness before examinations are not causes of glycosuria that need be taken into account. He has records of 141 persons in whom glycosuria was discovered at life insurance examination and who have been kept under observation for considerable periods, some as long as thirty-eight years, none less than four years. In one case diabetes was noted as a contributory cause of death, in two cases subjective symptoms of diabetes appeared later, and in eight cases re-examination established a positive diagnosis of diabetes. It is interesting to notice that accidentally discovered glycosuria is more often associated with a high alimentary blood sugar than with a low threshold value, thus corroborating the general opinion that true "renal diabetes" is rare. Again, these chance discoveries of glycosuria occurring without subjective symptoms of diabetes are made chiefly in competent individuals. The author believes there is such a condition as glycosuria innocens, but he warns us to investigate thoroughly before accepting a case as "innocent," especially because mild diabetes may show normal fasting blood sugar values. His work is a most valuable contribution to the clinical study of diabetic and non-diabetic glycosuria.

OIO RHINO-LARYNGOLOGY

It is evident that the time has come when it is scarcely possible to present a complete textbook of otology, rhinology, and laryngology within the limits of a single manageable volume. In the two books now under notice Dr. John F. Barnhill and Dr. Wendell Phillips have recognized this limitation.

By concentrating on the essentials and chiefly on the surgical aspect of the subject, though the medical side is not neglected, Dr. BARNHILL has, in his *Nose, Throat and Ear*,² continued to produce a well-balanced and magnificently illustrated account of the diseases of these regions and their immediate neighbourhood, as they are likely to present themselves to the practitioner or to the surgeon commencing hospital practice in this special department. The practical side is consequently uppermost, while theoretical considerations and references are excluded. The author has achieved a book which should be highly useful in the field indicated, though it is not one which the specialist is likely to keep for reference. No account of pharyngeal pouches, for example, is to be found, but as an introduction to the surgery of these regions the book is excellent.

Diseases of the Ear, Nose and Throat,⁴ by Dr. WENDELL PHILLIPS, now a standard textbook in America, has reached its seventh edition. Dr. Phillips states deliberately that the section on diseases of the ear is placed first to emphasize the fact that it is a complete work on otology. He has now expanded this with an elaborate consideration of the problem of deafness from the social standpoint, a problem which has in recent years received even more attention in America than in this country. The sections on general disease in relation to special regions and organs and on the nose are excellent, but the first section now overshadows the whole. The sections on the pharynx and larynx and especially the latter, seem to fall away and although it cannot be said that anything is definitely

lacking, they do not give the impression of being the first cure in the mind of the author as do the earlier sections. If all this must be included in one volume, by one writer, then Dr. Phillips's work is as satisfactory as any other large textbook, but it shows that, however successfully laryngology and rhinology and otology may be practised together, it is now extremely difficult to write evenly, and at the same time exhaustively, upon all three subjects.

BIOCHEMISTRY OF THE SKIN

Nearly twenty years ago Professor UNNA wrote a volume on the biochemistry of the skin, and we now have before us in his latest work, *Histochemie der Haut*,⁵ what is in reality a continuation of his researches on the same lines. The topics with which it is mainly concerned are the structure of the cell and the all-important processes of oxidation and reduction. By means of differential stains carefully chosen for their chemical affinities he is able to demonstrate the presence of acid and basic proteins and their relative situations in the cell. For example, the acid nucleo-protein is found near the periphery of the nucleus, while the basic globulin occurs in the centre. As a result of his work Unna has constructed a theory of cell structure, which he calls the "stockwork" theory. This, shortly, is that the cell is built up in three stories, consisting of a foundation of what he calls plastin, a very resistant material insoluble even in 15 per cent hydrochloric acid, a superincumbent story of mesoplastin, and finally of a much more labile substance of acid reaction, which may be either cytoxe, globulin, or nucleo-protein, or all three combined. Oxidation only takes place in the last story, while reduction takes place either in the plastin or mesoplastin, both of which are basic. It is difficult to summarize this matter shortly, and almost impossible to put it into language non-technical enough for easy comprehension, but it undoubtedly deserves the attention of all biochemists as well as dermatologists. This volume is a powerful witness to the evergreen energy and mental capacity of the venerable professor, who has now been at work for nearly sixty years; dermatologists may be proud that he is still reckoned as one of themselves. A word of praise is deserved for the figures (more than sixty in number), which are all coloured and well reproduced.

NOTES ON BOOKS

PROFESSOR TERREIN has completed the fourth of his series of volumes dealing with the symptomatology of ocular diseases, the first three of which dealt with the cornea and sclera, the iris and ciliary body, and the lens and its suspensory ligament. There is no denying the excellence of the series or the wide knowledge and clinical experience of the author. The present volume⁶ deals with the movements of the eyes, orthophoria and heterophoria, concomitant and paralytic strabismus and nystagmus. The last chapter appears somewhat as a surprise in a volume of this sort, and deals with exophthalmos and endophthalmos, which are considered as displacements of the eye as a whole. The subject is well and comprehensively treated, the physiological principles underlying the various clinical conditions are clearly and adequately set out, and the clinical descriptions and therapeutic recommendations are sound and trustworthy.

In a pamphlet entitled a medical excursion into foreign lands,⁷ Dr. HABERLAND, professor of surgery in the University of Cologne, has compressed in a small space his observations on medical matters made during a journey through North and South America, China, Japan, and the Philippines. Dr. Haberland is evidently a keen observer, bent on ascertaining what foreign countries have to teach his countrymen by way of improvement in medical matters. He notes a certain post-war lassitude in his countrymen, and advises foreign travel with a view to stimulating emulation and a determination to place German science in the commanding position it once occupied. Even in the limited space available he has collected a vast number of facts relating to general hygiene, hospitals, medical curricula, nursing arrangements, and research institu-

tions, he has also discussed the social position of medical men in the countries visited, and the prospects open to Germans proposing to settle abroad

L'homme impuissant, by the veteran professor of physiology in the University of Paris, CHARLES RICHER has been admirably translated by LLOYD HARVEY, but the title *The Impotence of Man*⁸ is ambiguous, and when submitted to a medical eye even misleading for, apart from one brief reference to sexual matters, it deals with general aspects, it might, indeed, have been better rendered 'Powerless Humanity'. Writing most pleasantly, but with a strain of "all is vanity," Professor Richet begins by showing man to be enslaved by the force of gravity and quite unable to visit the moon, Mars, or Venus, then he shows how little the struggle availeth by describing a library as a necropolis in which the thoughts of the dead repose quite undisturbed in their covers. This might sound like pessimism, but under the heading of "impotence and happiness" he reveals himself as the genial, laughing philosopher, for if we are very little in comparison with Sirius we are immense beside a microbe. In the chapter on physiological impotence Professor Richet writes charmingly as ever, but with a depressing fatalism. In the next chapter, however, on moral impotence, the reader is again a little reassured, and shown how he should deserve merit. In conclusion, Professor Richet returns once more to the relations of happiness and powerlessness, shows that they are not synonymous, and counsels humility and a philosophic outlook in order to be happy.

In his little book on *Infectious Diseases and Aseptic Nursing Technique*⁹ Dr D L RICHARDSON, who is superintendent of Providence City Hospital, Rhode Island, has provided nurses with a clear and concise account of the common infectious diseases, followed by a brief sketch of certain tropical diseases endemic in the United States or liable to be imported at any time, such as malaria, yellow fever, and plague. The work is divided into two unequal parts. The first and larger, consisting of fifteen chapters, contains a preliminary discourse on infection and immunity which is followed by a systematic account of the principal infectious diseases including gonorrhoea, syphilis, and tuberculosis. The second part, which deals with aseptic nursing technique, including methods of disinfection, is based on the methods which have been used with satisfactory results at the Providence City Hospital for several years. The work, which is thoroughly practical, will prove a useful introduction to nurses in their fever course.

In a lecture entitled 'Technique and effects of sympathico-diathermy on the arteries of the genital glands'¹⁰ Dr KARL DOPPLER, who is an assistant of Professor Lorenz at the Vienna Merchants Hospital, gives a description of a treatment which consists in painting the splanchnic nerve tissue with a 5 to 7 per cent solution of phenol. This solution has proved harmless to the surrounding tissue. During the last two years Dr Doppler has treated over 200 patients of both sexes with success, the patients regaining mental and physical health within three or four weeks. The operation is said to be indicated in conditions due to endocrine deficiency, or to hypertonus of the sympathetic, or, lastly, to the not infrequent combination of both factors.

It is a trite remark to say that individual patients require individual attention, and it follows that almost any scheme designed to standardize treatment by means of printed instructions is unlikely to succeed. At the same time some of the 'Instructions for Patients'¹¹ recently produced by Dr T T B. WARSOV have their use. Such therapeutic procedures as the application of hot fomentations or washing out the eyes may well be described in a leaflet to be given to the patient to enforce the spoken word. In the case of other subjects dealt with in this series, such as the treatment of gonorrhoea or exercises for constipation or diet in obesity, it seems to us very doubtful whether printed slips give enough latitude for the individual doctor's opinions or the individual patient's physical and social conditions. So far eight such slips of printed instructions have been issued, and eight more are in preparation. They are printed on separate sheets, with an outside cover bearing on the front the title and inside some remarks intended for the doctor only. The slips for patients are meant to be torn out as required. Within the limits specified above such instructions have some use, and in the present series clarity and simplicity have certainly been attained.

We have received a copy of the *Standard Methods*¹² used in the New York State Department of Health laboratories, of which Dr AUGUSTUS B WADSWORTH is the director. The work is divided into six parts, a description of general laboratory procedures being followed by an account of the methods used in the department for the preparation of media and glassware, in the diagnostic laboratories, in the laboratories for sanitary and analytical chemistry, in the laboratories for antitoxin, serum, and vaccine, in the executive offices, and in the research publications and library departments. A bibliography of 168 references is appended. The work will be invaluable to the research worker, and should form part of the library of every laboratory.

Among the very many medical bridge players there are perhaps some who regard themselves as beginners, and these may like to know of the appearance of a little book entitled *Auction Bridge Lessons for the Uninitiated*,¹³ by MAJOR TENACE, of which a copy has been sent to us for notice.

PREPARATIONS AND APPLIANCES

LEAD FOIL STRAPPING

For the prevention of injury to healthy skin surrounding small growths and areas which are being treated by means of x rays or radium, a protective material has been devised by Dr J H TWISTON DAVIES (Brighton), and is supplied by Leshes, Ltd., 104A, High Street, Walthamstow. It consists of a special adhesive strapping backed with lead foil 0.3 mm. thick. If the lesion is outlined in ink and a piece of the strapping applied immediately, the latter will on being removed show an outline of the lesion which can easily be cut out with a sharp knife. Thus the user is provided with an accurately fitting lead shield, which retains itself in position by virtue of the same material which also acts as a screen for the secondary radiations given off by the lead.

A METHOD OF FINISHING SURGICAL SUTURES IN HALSTEAD'S

INTRADERMIC STITCH

Mr Milroy Paul, FRCS (Colombo), describes a method of finishing surgical skin sutures which he has devised. He writes: The method is simple and efficient, and has been found to be satisfactory in practice as a neat way of ending surgical skin sutures. For Halstead's intradermic stitch it is much superior to the method of tying the two ends over a gauze plug placed over the wound, it is considerably better than the procedure of clamping perforated lead shot on to the suture as it emerges from the skin, and is without the disadvantage of

requiring special apparatus. The method consists of passing a suture round the skin suture as it comes through the skin (Fig 4). It is an advantage to have the suture *b* (Fig 4) much thicker than the skin suture *a*, since the resulting knot is thereby sufficiently big to eliminate the risk of its being pulled through the stitch hole. The two ends of the suture *b* are knotted together, as in Fig 5, and then one of the ends of *b* is knotted to the skin suture *a*, as in Fig 6. In Fig 1 is shown a Halstead's intradermic stitch, loosely inserted with the end coming through the skin, where it can be tied off as in Figs 4, 5 and 6. In Fig 2 is illustrated a simple continuous suture. In Fig 3 a mattress suture is depicted with the end coming through the skin and ready to be tied off.

ROYAL COMMISSION ON LOCAL GOVERNMENT.

THE SECOND REPORT RELATION TO THE REFORM
PROPOSALS

In deciding upon the preparation and issue of their second report the members of the Royal Commission on Local Government of which the Lord of Onslow is chairman, have been actuated by the desire to make public their recommendations on certain outstanding questions which are to be the subject of early legislation. An account of the Government's proposals for the reform of local government was given in the *Journal* last week (p. 765), together with a brief note on the views of the Royal Commission.

It may be recalled that the Commission, which was instituted early in 1923, issued its first report—dealing with the constitution and extension of county boroughs—in August, 1925, and thereafter turned to the second part of its task—to investigate the relations between the various types of local authorities, and to make recommendations as to their constitution, means, and functions. The publication in December, 1925, of the provisional Poor Law reform proposals interfered with the original programme of proceedings, and in April this year the announcement of the Government's intention to execute the reform measures to which we referred last week made it necessary to reconsider once more the task before the Commission. It was decided, after consultation with the Ministry of Health, to concentrate upon certain specific questions on which it seemed desirable that the Commission's conclusions should be known before the introduction of the proposed new legislation. These questions, on which a considerable body of evidence had been heard, related to the reorganization of areas, to measures to assist or to stimulate authorities unable or unwilling to function, to the distribution of functions, and to the appointment of whole time medical officers of health. These matters are the subject of recommendations in the report now under review.

The evidence heard by the Commission was furnished mainly by representatives of associations of local authorities—county councils, municipal corporations, urban district councils, and rural district councils. Sir Arthur Robinson also appeared on behalf of the Ministry of Health on two occasions, dealing on the second with the need for accelerated progress towards the appointment of whole-time medical officers, and with the distribution of health functions among local authorities. A summary of his evidence was given in the *Journal* of September 29th (p. 575). In the *Supplement* of the same date (p. 142) we published a memorandum of evidence on these questions prepared by the British Medical Association for submission to the Royal Commission. Owing, apparently, to the fact, as explained above, that the Government's policy matured into action more speedily than the Commission was able to overtake its task, the Association has had no opportunity of giving oral evidence. Presumably, however, its views received due weight. The report states that the members had the advantage of considering memoranda which have not been the subject of oral evidence, and do not appear in the published minutes of evidence, but have none the less contributed to the solution of the questions before us.

Whole-time Public Health Appointments

Two of the main questions on which the Commission concentrated attention are of considerable importance to the medical profession—the acceleration of progress towards whole time appointments of medical officers of health, and the distribution of functions among local authorities. There was, it appears, general agreement among the representatives of local authorities that whole time service was desirable. This meaning

the appointment of a medical officer who is precluded by the terms of his service from engaging in private practice, and who therefore gives his whole time to public duties, though not necessarily in the service of a single local authority. The Commission agreed that steps should be taken to facilitate the

progressive adoption of such appointments, and expresses the view that an essential means of securing this is to provide that the question of making a whole time appointment should be considered as and when each individual vacancy for a medical officer of health occurs. It is accordingly recommended that statutory provision should be made to require each county council, in consultation with the county district councils, to frame for the whole county a scheme for the appointment of whole time medical officers of health. The Commission also proposes that when a part time appointment for a county district falls vacant, the council, after consultation with the county council and any other district council, should be required to appoint a whole time medical officer, either solely or jointly with the county council or other local authorities. Discretion should, however, be given to the Minister of Health to waive in special circumstances the requirement precluding private practice.

Maternity and Child Welfare

In discussing the distribution of functions between local authorities the Commission takes the view that the chief factors to be considered should be population, area, financial capacity, and efficiency, in which connexion the staffing of the local authority is an important consideration. Attention has been directed in the first instance to the co-ordination of services affecting the welfare of mothers and children. It is recommended that the school medical service should remain in the hands of the local education authorities, as determined by the Education Act, 1902, and that where school medical authorities are not now responsible for maternity and child welfare work, the Minister of Health, on representations from the school medical authorities or the county councils, should be empowered to order the transfer of this service to them. The Commission suggests, further, that the authority responsible for the administration of the Notification of Births Acts should be required to send forthwith a duplicate of every notification to the maternity and child welfare authority of the area. The recommendation is made that a maternity and child welfare authority employing a whole time medical officer of health should be permitted to represent to the Minister that it should be constituted local supervision authority under the Midwives Act, county councils being empowered to apply for the retransfer of this service to them on administrative grounds. Regarding the ascertainment and treatment of ophthalmia neonatorum, it is proposed that this work should be assigned in each area to one authority, that this should be the authority responsible for providing the treatment, and that responsibility for treatment should be placed upon the maternity and child welfare authority.

Hospitals for Infectious Diseases

The Commission considers that county councils should provide and maintain small pox hospitals, adding the proviso that where other arrangements are working satisfactorily they should not be disturbed. In the case of other isolation hospitals it should be the duty of the county council to see that adequate provision exists, to draw up a scheme for the purpose in consultation with the local authorities, and to frame proposals for further provision or reorganization where necessary. Statutory safeguards, on the lines laid down by Parliament in the Public Health (Tuberculosis) Act, 1921, should, it is held, be provided against the failure in future of any responsible local authority to make adequate arrangements for the provision and maintenance of infectious diseases hospitals.

Organization of Areas

The main recommendation of the report in the general field refers to the reorganization of local government areas, in which connexion the Commission suggests the institution of a general review of existing county districts and parishes, involving the preparation by the county councils of proposals for any boundary alterations or unification measures found necessary. Suggestions are also formulated regarding the extension of the local area of charge for certain services, notably water supply and sewerage.

Default Powers

The Commission has given some consideration to the revision of powers of stimulus and default powers, and it suggests that the existing legislation should be amended to provide that it

would rest normally with a county council, in the first instance, to draw the attention of the Minister of Health to the existence of unsanitary conditions, the Minister should be required to consider any such recommendation, and empowered to institute a local inquiry. To meet the case arising if a local inquiry has established the fact that a county district council is not administering a health service up to a reasonable standard, and has not taken satisfactory action within a fixed period, it is proposed that there should be statutory powers for (a) the relinquishment of responsibility by the county district council to the county council by agreement and with the approval of the Minister, (b) the performance of the work by the county council, the district council repaying the cost as a debt, or (c) the transfer of the service by order of the Minister to the county council, either for a stated period or until the revocation of the order.

THE STATE OF THE PUBLIC HEALTH

SIR GEORGE NEWMAN'S REPORT

[SECOND NOTICE *]

Veneral Disease in England and Wales

At the close of 1927 there were 185 veneral disease treatment centres in England and Wales. Only five of these provide all-day facilities, it is hoped to add to their number during the present year. Maternal and child welfare centres arrange treatment for syphilis and gonorrhoea in expectant mothers, and thus help to prevent congenital syphilis and ophthalmia neonatorum. As syphilis is the direct cause of 10 to 15 per cent of the blindness in the country, and ophthalmia neonatorum of 20 to 30 per cent of that in blind schools, the present decrease in the number of blind persons in the age groups up to 21 may be attributed to the work of these centres. The total attendances in 1927 at veneral disease clinics were 46.4 per cent more than in 1920, though the total new cases were 17,049 (16.2 per cent less). This means that defaulting before completion of treatment is less than it used to be. In His Majesty's Forces, where concealment of veneral disease is forbidden, the ratio of new notifications with gonorrhoea to those with syphilis is 6 or 7 to 1. In the centres the ratio is far smaller, especially in the case of female patients, and it is impossible to avoid the conclusion that a considerable proportion of women suffering from gonorrhoea fail to come for treatment. Analysis of the results of treatment of male syphilis at the St Thomas's Hospital centre shows that even in primary cases, in which serum reactions have not yet become positive, less than two courses of ten injections each of "914" and of bismuth results in too high a percentage of relapses, while three such courses are barely sufficient for early cases in which the blood reactions have become positive. These analyses show clearly the great advantage of commencing treatment while the serum reactions are still negative.

Sir George Newman discusses in some detail the question of compulsory notification of veneral disease. The procedure in relation to acute infectious diseases cannot, he holds, guide us in this matter. These diseases are of relatively short duration, and the purpose of notification is to permit health authorities to protect the community by isolating the infectious person and disinfecting his house and clothing. But syphilis and gonorrhoea may pass through various stages of infectivity over a long period, making it impracticable to define the notifiable stage of the disease. Furthermore, medical practitioners are reluctant to notify veneral disease, both on account of the social stigma attaching to it and through fear of inflicting irreparable social harm upon innocent individuals and families. It is also suggested that patients are likely to evade notification by seeking treatment from quacks (promising secrecy) rather than from veneral disease clinics and hospitals. The idea of compulsory treatment is condemned, not only on the general principle of respecting individual liberty, but on

the ground that it will increase the dangerous incentive to concealment. Objection is likewise taken to coercive action in relation to the defaulter—that is, the person who starts but does not continue treatment for venereal disease. Syphilis and gonorrhoea must not be artificially separated from all other diseases, and so long as no coercion is applied to those who begin but do not finish a bottle of medicine, who undergo but do not continue dental treatment or treatment for tuberculosis, it is illogical to suggest that exception must be made in the case of venereal disease. Moreover, the syphilitic defaulter, long before he can be declared completely cured, has often become non-infective.

Cancer

The fallacy of assuming a great increase in cancer incidence from cancer mortality statistics is emphasized. More deaths are attributed to cancer than formerly, owing to the changed age distribution of the population and greatly improved technique of diagnosis. The steady annual increase in the recorded death rate continues, the number in 1927 being 54,078, or 1,376 per million persons living. But the question whether this represents a real increase in cancer remains unanswered. The prevailing fashion of correlating all forms of cancer with some general etiological factor, such as dietary excess or defect, is criticized, and the suggestion is made that it would be better to confine investigation to a single organ at a time, in order to ascertain whether cancer of this organ is increasing or decreasing, and if so for what reason. The possibility of some causal factor of general application—diet, race, climate, etc.—is not ruled out, but regarded as unimportant compared with the local factor affecting the organ concerned and arising during the individual's lifetime. Analyses of results in the treatment of cancer of the cervix uteri indicate that irradiation already has some advantage over surgery, and may have more in the future.

Maternity and Child Welfare

Continued progress is reported in the schemes for maternity and child welfare. The total number of infant welfare centres in 1927 was 2,341, compared with 2,324 in 1926. There were also 847 ante-natal clinics approved by the Ministry of Health. Sir George Newman expresses the view that adequate ante-natal supervision, with the assistance of the municipal clinic or the maternity hospital, is the only sound foundation on which an effective maternity service can be built. He suggests that every ante-natal clinic should be organized in close association with a hospital, to which patients can be referred if necessary. Every pregnant woman should receive a sufficiently thorough examination to ensure detection of complications, and be kept under close observation during the last weeks of pregnancy. Furthermore, vaginal discharges and other sources of sepsis should be investigated and treated, and a routine Wassermann test performed. The importance of notifying all cases of puerperal pyrexia is again emphasized. The origin of such pyrexia is not necessarily sepsis, but the only safe rule is to regard a case as septic until the contrary has been proved.

The Insurance Medical Service

The insurance medical service in England and Wales comprises 14,956 practitioners, dealing with 14,363,000 patients. The average number of persons on a practitioner's list is 928. During 1927 56,527,555 prescriptions for insured persons were dispensed by 9,584 chemists. Much of the increase in the cost per head of medicine and appliances is attributed to lack of due consideration for economy on the part of some practitioners. Medicine is prescribed for a week when enough for two days only is required; costly proprietary preparations are ordered instead of equally effective official remedies. The number of complaints against insurance practitioners investigated in 1927 by the Insurance Committees was 309, as compared with 291 in 1926, 72 cases, in 3 of which there was a successful appeal, were decided against the practitioners. Most of the cases were trivial. Schemes for giving post-graduate instruction to insurance practitioners have been in operation in twenty-five areas. These have provided post-

* The first notice of the Annual Report of the Chief Medical Officer of the Ministry of Health for the year 1927 appeared in the *Journal of October 27th* page 753.

graduate facilities for a hundred practitioners, but more extended provision is being made this year. There has again been an increase in the number of sickness claims, the total expenditure on benefits being £15,089,000, as compared with £14,169,000 in 1926. The steady rise in this expenditure is accounted for by the larger proportion of elderly persons in the insured population, by increased susceptibility to illness following prolonged unemployment, by growing awareness on the part of employed persons of the advantages of the insurance system, by the unrestricted freedom of the insured person to change his doctor, and by changes in the personnel of the insurance medical service.

Nutrition

So many firms now claim that their preparations contain vitamins that, for the protection of the consumer, it is suggested they should obtain an impartial and reliable guarantee of the accuracy of their statements. A margarine containing vitamins A and B is thus tested by the Pharmaceutical Society, and a certificate supplied to the manufacturers is renewed each month on the results of the tests. The consumption of milk per head of population is about 0.4 pint daily. This rate should be at least a pint, but cannot be attained till those behind the "Drink More Milk" campaign support their own efforts by providing a satisfactory and attractive article. The danger of tuberculous infection from milk, and the consequent need to safeguard the health of dairy cattle, to examine milk for tubercle bacilli, and to exercise sanitary control over dairies, is duly emphasized. During 1927 some forty food-poisoning occurrences were reported. It seems likely that minor cases, of the kind too mild to be recorded, are not due to the *Salmonella* group, skilled investigation into their nature is desirable.

Work of the Pathological Laboratory

Work on the serological classification of haemolytic streptococci from the throats of scarlatinal patients has given further evidence in support of the view that these organisms are the cause of scarlet fever. The classification of haemolytic streptococci into five groups, of which Type 2 (found commonly in connexion with scarlet fever) is responsible for most of the cases in which complications occur, and Type 4 produces a mild disease, together with the possibility of successive infections by these types, may help to explain some puzzling features in the clinical diagnosis of scarlet fever and its subsequent course. Work on the etiological significance of the pneumococcal types has been continued. It is very rare to find carriers of Types 1 and 2, except in contacts with disease due to these types, Type 3 is carried with variable frequency, Type 4 commonly.

Liver Extracts in Pernicious Anaemia

In 1921 Whipple and Robscheit-Robbins showed that blood regeneration in dogs is hastened on a diet containing liver and other iron-rich foods. This suggested to Minot and Murphy the treatment of pernicious anaemia by a well-balanced diet, especially rich in liver. They reported favourable results in 45 patients in 1926, and in 60 more in 1927. These results have been confirmed by many observers in this and other countries. So far the evidence as to the effect of the treatment on associated nervous lesions is indecisive. A minority of cases failed to respond, and this suggests that pernicious anaemia may not be a haemolytic condition, but one due to inability of the blood-forming organs to utilize bilirubin. It is not yet known if patients will be able safely to stop the treatment, or, indeed, if they will continue to respond to it for an indefinite time.

Acute Rheumatism

An experimental trial of compulsory notification of rheumatic fever over a definite number of years in selected districts which comply with certain conditions is suggested in the report. These conditions are that the housing and other records of the local authority are accurately kept, that efficient machinery exists for investigating notified

cases, and that institutional treatment is available. Various rheumatic supervisory centres are investigating the etiological significance of housing, damp, environment, heredity, social position, and condition of school life, and the clinical significance of tonsillectomy and institutional treatment, but more extensive work of this kind is urgently called for. The report stresses the need for co-ordinating investigation of this malady and of a systematic attack on it, as a vital measure in the prevention of heart disease and disease of the nervous system. Probably 40 per cent of deaths from heart disease result from acute rheumatism contracted during school age. Recurrent attacks are usual, but the tendency to recurrence may be minimized by three months' institutional treatment during the acute attack, and at least six months' convalescent treatment and after-care to follow. With regard to the chronic rheumatic diseases, which cause nearly one-sixth of the total invalidity covered by insurance benefit, the difficulties in the diagnosis and treatment of this group of diseases are clearly set out, and it is suggested that if they are to be overcome the formation of "arthritis units" is almost indispensable.

Artificial Light Therapy

For the past three years the Ministry of Health has encouraged the provision of artificial light treatment by local authorities. The conditions laid down are, that the treatment shall be under medical supervision, and that those approved to administer it shall be practised in technique and acquainted with the dangers of the procedure. It is pointed out that unskilled technique may be followed by skin burns, cataract, conjunctivitis, etc., and that considerable knowledge is required in the choice of patients for treatment. Set routine in the matter of exposure and number of attendances is deprecated, each case must be treated on its merits and according to the sensitiveness of the patient. In the infant welfare centres the best response is given by (a) flabby, debilitated, underweight, fretful babies, (b) cases of early rickets, (c) cases of malnutrition. Many observers report cases that have been rendered worse by irradiation. After discussing the therapeutic uses of ultra-violet rays in skin disease, rickets, asthma, lupus, surgical tuberculosis, etc., Sir George Newman concludes with the suggestion that this therapeutic method is unlikely to prove more than an adjunct to other forms of treatment, and that for prevention of disease one must look rather to adequate food and housing, open air exercise, fresh air, and natural sunlight.

International Health

The Office International d'Hygiène Publique has entered into an agreement with the Health Committee of the League of Nations to avoid overlapping in work, this and several similar agreements have resulted in the establishment of a world-wide system of immediate intelligence regarding the prevalence of cholera, plague, yellow fever, small-pox, and typhus. Consideration has been given to proposals for unifying quarantine flags and signals, and for establishing an annual international record of the sanitary equipment of seaports, and like matters.

Health Education

Sir George Newman ends his report with a consideration of methods for improving the education of the public in matters of individual and public health. The educational work carried out by voluntary effort is of great value, but this does not absolve local authorities from their responsibility. They should regard education in public health as at least of equal value to any other form of health work they undertake. Among the principal direct methods suggested are the publication of pamphlets, posters, and so forth, the preparation of articles for the press, lectures and educational classes, the use of the cinema, and broadcasting. But the best form of popular education is effective administration of the public health services concerned. The sound practice of the science and art of preventive medicine is the supreme method of instructing the community.

SATURDAY, NOVEMBER 3RD, 1928.

NEUROLOGICAL PROBLEMS OF TO-DAY

ALL neurologists, and many others, will be grateful to Dr Kinnier Wilson for having collected in one volume a number of his recent contributions to the literature of neurology, which have hitherto been available only in the journals in which they were published. His title, *Modern Problems in Neurology*,¹ is justified by the fact that the work embraces in its scope all the questions of importance to which neurological research is at present endeavouring to find answers. The first chapters deal with "the epilepsies," and are followed by a discussion of what he believes to be a closely allied condition—the symptom narcolepsy. Then come six chapters devoted to the symptoms of disorders of the corpus striatum, including the author's Croonian Lectures for 1925. The last three chapters are concerned with pathological laughing and crying, dysaesthesiae—or paraesthesiae, as they are sometimes called—and the Argyll Robertson pupil. To the discussion of these problems Dr Wilson brings a large clinical experience, a philosophical outlook, and a lucidity of style which is unfortunately too rare in medical literature.

Dr Wilson speaks of "the epilepsies" in the belief that epilepsy is a symptom which may be evoked by a variety of pathogenic agencies. The heterogeneity of "epilepsy" has certainly been insufficiently recognized in the past, and may justifiably be emphasized, in a previous reference to Dr Wilson's views (April 7th, p. 601) we agreed that the epilepsies might well be regarded as symptoms. But he tends perhaps, to under-estimate the importance of the underlying constitutional factor, for which there is considerable evidence in some cases. In stressing the local cerebral state responsible for a convulsion the possibility must not be overlooked that metabolic abnormalities may contribute to bring this about. Though neurophysiology has by no means come to the end of its contribution to the study of epilepsy, the biochemical investigation of the conditions regulating the reactivity of the nerve cell is still in its infancy, and is full of promise.

The role of inhibition in neural function is a problem the study of which has lately received an impetus from Pavlov's researches on conditioned reflexes. It has bearings upon many normal and abnormal phenomena. Inhibition appears to play a part in the loss of consciousness which characterizes an epileptic fit and may be an essential element in the "attacks" of narcolepsy and cataplexy. Normal sleep, hypnotic suggestibility, and psychological repression may also be aspects of inhibition. Dr Wilson deals with some of these topics, he regards narcolepsy and cataplexy as closely akin to the epilepsies rather than as pathological forms of sleep. There is much work to be done before clinical neurology can assimilate Pavlov's conceptions concerning inhibition which at present raise more problems than they solve and it will be wise, we think, to suspend judgement on many of these difficult questions.

Dr Wilson's views on the functions of the corpus striatum naturally arouse special interest for his recognition of progressive lenticular degeneration first

focused attention on these mysterious structures. Since then a great diversity of opinion has arisen as to their functions, and many workers, especially on the Continent, have credited the corpus striatum with complex motor activities. Dr Wilson contests this view, and is unable to find any evidence that the striatum is a "centre" for emotional expression, associated movement, muscular synergy, or other such complicated functions. For example, he argues that the apparent reduction or loss of certain types of movement in Parkinsonism is due merely to the hampering effect of the rigidity. The impaired movements such as arm swinging in walking are not performed because, owing to the patient's rigidity, they involve considerable effort. Dr Wilson's conception of the functions of the corpus striatum is a simple one: he believes that this structure has the twofold function of controlling muscle tone and of inhibiting a neuro-muscular rhythm which, when not held in check, manifests itself as tremor. Many neurologists will regard his theory of striatal function as being, like the Parkinsonian patient, hampered by its rigidity. Clinical observation suggests that the relation between loss of movement and hypertonia in striatal disease is by no means as close as he maintains. Weakness, slowness, facial immobility, and loss of arm swinging may all make their appearance in Parkinsonism before the rigidity to which they are attributed. Dr Wilson's chapter on pathological laughing and crying is an admirable analysis of these remarkable disturbances, but it, too, suffers from his conservative view of striatal function, for he attributes the escape of emotional reflexes from voluntary control exclusively to lesions involving cortico pontine and cortico bulbar paths, in spite of the well known fact that pathological laughing and crying may be associated with striatal lesions, as he himself showed in his monograph on progressive lenticular degeneration. His views, then, are critical rather than constructive, but in the current state of neurological theory concerning the corpus striatum destruction is an essential preliminary to sound building. This indirectly constructive work of the critic is seldom appreciated at its true value.

We have outlined above some of the principal problems which confront the neurologist at present. It is natural to conclude with an inquiry as to the direction in which we may look for their solution. Comparative physiology received an immense impetus from the Darwinian emphasis upon man's animal characteristics. The neurologist nowadays however is constantly being reminded of human uniqueness. Man's erect attitude sets a wide gulf between himself and his nearest simian relatives and it is becoming increasingly evident that there are many human neural activities upon which experiment, even though apes and monkeys be the subjects, can throw little or no light. Disease and war are the great experimenters in human physiology, but the size and often the multiplicity of the lesions produced by these blind and careless workers renders the task of drawing physiological deductions from pathological states extremely complex. But the refractoriness of his material merely adds zest to the work of the artist and it is to an element of art in neurological, and indeed in all medical research that we would draw attention in conclusion. Neurology has always proved attractive to minds of philosophical outlook for the neurologist has continually to deal in a practical way with those problems of the relations of body and mind which exercise the philosopher in the rarefied atmosphere of his study. Men of this type, of whom Hughlings Jackson is the supreme example, are constitutionally

¹ *Modern Problems in Neurology*. Dr S. A. Kinnier Wilson, M.D. F.R.C.P. London: E. Arnold, 1928. (Demy 8vo pp vii + 364 56 figures 21s net.)

impelled to seek in the chaotic world of phenomena for the operation of general principles. Havelock Ellis, in his book *The Dance of Life*, has pointed out that his creative element in science and philosophy is as much an art as the creative activity of the artist. While the physiologist, the anatomist, the pathologist, and the clinician have still their parts to play in neurological research, their findings will be of little value in the absence of men who by nature and training are qualified for "the art of thinking."

THE PANEL CONFERENCE

THE proceedings of the Conference of Representatives of Local Medical and Panel Committees, which we report fully in this week's *Supplement*, were less interesting and less important than has usually been the case. This fact is somewhat surprising since, although a number of good reasons may be given for it, the reports which the Insurance Acts Committee presented to the Conference contained full references to matters which may be of the most vital consequence in connexion with insurance administration and with future developments of the national health insurance service. What used to be the annual challenge to the recognition of the Insurance Acts Committee as the authorized mouthpiece of insurance medical practitioners in consultations and negotiations with the Government is no longer forthcoming. The persistent minority which formerly issued this challenge has wisely accepted the position of the Insurance Acts Committee as no longer open to question. Further, there seems no disposition on either side at present to reopen the question of the amount of the capitation fee or the mileage fund in accordance with which the insurance practitioners' remuneration shall be calculated. There has been, too, a certain stabilization of the regulations affecting the ordinary work of insurance practitioners, and an agreement that for a period of years they shall not be altered without consent. Almost all the difficulties and disputed points concerned with day by day practice have been adjusted as experience has shown the need, thanks to the continued exertions of the Insurance Acts Committee and the usually sympathetic consideration of the Ministry of Health. In these circumstances a certain diminution of liveliness at the Annual Panel Conference of 1928 is not a matter for wonder.

Yet there may be some room for disquietude when a broad review of the proceedings leaves as its main impressions a passive rather than an active support of the arduous work of the Insurance Acts Committee throughout the year on the part of the main body of the Representatives, a merely meticulous, even at times querulous, criticism of that work from a section, and a certain sameness and restriction of outlook which contrast, on the whole, unfavourably with that usually shown during discussions in the Insurance Acts Committee itself in the Council of the British Medical Association, and in the Representative Body. It is curious that it was in this atmosphere, and not under more momentous or controversial conditions, that the Conference, for the first time in its history, adopted a resolution which was in form (though not, it seems, in intention) a direct vote of censure on the Insurance Acts Committee for action which it had taken. This resolution certainly produced the best debate of the Conference, but the debate was mainly directed not to the resolution on which the vote was taken, but to a wider problem which the mover of the

resolution himself admitted lay wholly outside the province of the Committee and the Conference. It will be remembered that the Council of the Association submitted to the Representative Body a national arrangement with the Manchester Unity of Oddfellows as to the capitation fee for attendance on juvenile members of that order, and that the Representative Body, as was its prerogative, decided the matter in such a fashion as to forbid the conclusion of such a national agreement but to permit of local agreements of a similar kind. The Council, before deciding on its recommendation, asked the Insurance Acts Committee for its opinion as to the effect of such an arrangement upon the question of the capitation fee for insurance work. There can surely be no dispute that this was a wise precaution to take, and a perfectly proper question for the Committee to answer. What the Conference intended to do, and what it undoubtedly did by a majority, was to express the opinion that the national bargain that had been proposed was an unwise one to enter into—a question which was admittedly not within its province in its wider aspect, and which had already been finally determined by the body whose province it was to decide. Yet what stands on record is the opinion of the Conference that the Committee should not have given its advice to the Council at all, and that its advice on the particular and narrow point submitted to it was wrong, although it is the only body of experts in existence possessing that experience of negotiations which can lend authority to such an opinion. This is manifestly absurd.

The most remarkable fact about this year's Panel Conference, however, is what it did not do. About one third of the report submitted to it by the Insurance Acts Committee was concerned with the administration of additional treatment benefits and the effect of the recent amending Act of Parliament in relation thereto, yet not one word on this subject was said from the beginning to the end of the Conference. Since, owing to the obstruction of the approved societies, the establishment of a consultant, specialist, and pathological service in connexion with the insurance scheme has been relegated to a distant future, it is the policy of the Ministry of Health to extend these services as far as possible by the method of additional benefits. The disadvantages of this are obvious, its dangers, especially to the consultant branch of the profession, are great. The conditions of service to be established during the next few months may have a vital effect on the future of several branches of professional work. Nevertheless the Conference appeared to feel no concern about this matter, and it can scarcely be said that its present membership comprises adequate representation of the interests affected. This is a thing of much importance since, as we have indicated, it is probable that questions relating to these extensions of the insurance service will be more prominently before us in the immediate future than questions relating to the general practitioner service such as have hitherto been the main subjects of consideration. Happily both the Insurance Acts Committee and the Council of the Association are fully alive to the importance of these questions. The Council has already asked the Committee to set up a special subcommittee, with a thoroughly representative personnel, to consider them, and it is to be hoped that by this means the interest of consultants themselves may be more fully aroused, and that more adequate attention may be given to such matters at future Conferences.

THE PREVENTION OF PUERPERAL MORTALITY

A FURTHER step of considerable importance has been taken in the campaign against puerperal morbidity and mortality which was inaugurated by the British Medical Association early in 1925, when it set up a special committee of inquiry. Realizing the many possible factors in the incidence of puerperal sepsis, this committee held a conference with representatives of official bodies directly interested, an interim report was published in the *Supplement* of January 9th, 1926, and the final report appeared as an appendix to the Annual Report of Council, published in the *Supplement* of April 28th, 1928. To grapple with the whole problem the Minister of Health appointed a departmental committee, wholly medical in composition; the names of its members were given in our issue of June 9th, 1928 (p. 998). The departmental committee was invited to draw up a form of inquiry for medical officers of health in their investigations of maternal deaths, and this step has now been taken. The form, which has been issued to maternity and child welfare scheme authorities in England, is accompanied by a circular (No. 934) and an explanatory note by Sir George Newman, chairman of the committee, who suggests that copies of both the form and the note should be sent to every private medical practitioner, inviting his collaboration in an investigation the aim of which is to improve the maternity service of the country. The first point emphasized is that all information recorded on the inquiry form will be treated as strictly confidential, it will only be communicated to the medical officer of health and to the Ministry for public health and scientific purposes. Any such information utilized in a report will be stripped of all identifying details. The procedure amounts, in short, to a consultation between one medical practitioner and another, and is, therefore, of a strictly private nature. Sir George Newman adds that the rules of professional courtesy must be observed, both in the letter and the spirit, and that due care must be taken to avoid any appearance of criticism of those concerned in the professional conduct of any case. In view of the disturbance to a doctor caused by a maternal death in his practice, it is admittedly essential that the attitude of others should be sympathetic and not critical. The inquiry, therefore, is emphatically not judicial, but scientific, and the relationship between the medical practitioners concerned is one of friendly co-operation. To this end it is provided also that the names of doctors and patients need not be included in the reports submitted to the Ministry by medical officers of health. Moreover, it is suggested that, if the medical practitioner in charge of the case so desires, the findings of the medical investigator should be shown to him for his observations before the medical officer of health draws up his final report for the Ministry. The more common causes of death are grouped together in the form, and various questions are placed under each heading with a view to suggesting appropriate lines of inquiry. Much of the information required in any case will be available already from various sources, and the remainder will usually be obtained at an interview between the general practitioner and the medical investigator. When a patient dies in an institution it is hoped that the authorities of it will be willing to furnish the necessary information, but the responsibility for obtaining the history of the case before admission will remain with the medical officer of health. It is further laid down that the medical officer of health concerned should be either that of the local supervising authority, or the maternity and child welfare authority, and should not be engaged in private practice; the inquiry so far as medical data are concerned, should be conducted by himself, either alone or with the assistance of some competent registered medical practitioner. Sir George Newman adds that in areas where

no recognized obstetrical specialist is available to assist the medical officer in such inquiries, it may be desirable to invite the local Division of the British Medical Association to nominate one or more practitioners whose services could be available if necessary. While modifications of the form may be thought desirable by individual local authorities, it will obviously be convenient for the data relating to maternal deaths to be collected in a generally uniform manner, and Sir George Newman hopes that similar arrangements will be made in all parts of the country. If in any case the local authority finds that the proper investigation involves additional expense, the Minister of Health will be prepared to approve reasonable expenditure necessarily incurred for this purpose. With the co-operation of all concerned a mass of information will gradually become available, which may serve as the foundation for a preventive work of the greatest value. If the lines suggested by Sir George Newman's circular and the Committee on Maternal Mortality are followed sympathetically in every area, there can be little doubt that a great step forward will have been taken in a campaign in which both the medical profession and the public are acutely interested.

AWARD OF THE NOBEL PRIZE TO DR CHARLES NICOLLE

THE recent announcement in the daily press that Dr Charles Nicolle, director of the Pasteur Institute of Tunis, has been awarded the Nobel Prize for medicine for 1928 in recognition of his work on typhus fever will be a source of gratification to all interested in the progress of medicine and to epidemiologists in particular. Dr Nicolle's researches on the causation and prophylaxis of typhus, which have been carried on for nearly a quarter of a century, were first undertaken in connexion with an epidemic which occurred in Tunisia in 1906-9, when he was able to show that the chimpanzee could be infected with the typhus virus by the injection of a small amount of blood from a patient in the acute stage of the disease. Subsequently he found that the lower apes could be similarly infected by inoculation of the blood of the chimpanzee, and that the infection could be transmitted from monkey to monkey by the bites of infected body lice. The demonstration of the louse as the agent in transmitting the disease was of far-reaching importance, and, like Dr Nicolle's other investigations, it was confirmed by workers in the United States and in other countries. Dr Nicolle also found that the guinea-pig could be successfully inoculated by injection of typhus blood. Although this animal showed no sign of disease as the result of inoculation except by a rise of temperature, it served a useful purpose in forming a storehouse of the virus for laboratory purposes. Of greater practical importance was Dr Nicolle's discovery that injection of the serum of patients convalescent from typhus was able to confer an immediate though transient immunity to the disease. A similar protective quality in the serum of convalescents he also showed to be present in the case of undulant fever and also in that of measles some years before Degkwitz made the method popular throughout Germany. One of his latest contributions¹ indicates that Dr Nicolle, in collaboration with Drs Sparrow and E. Conseil, is conducting experiments on active immunization against typhus whereby a more permanent immunity can be conferred. In addition to his article on typhus written in conjunction with Dr E. Conseil in the *Nouveau Traité de Médecine* of Roger, Vidal, and Teissier, Dr Nicolle is the author of numerous contributions on infectious diseases, including measles, influenza, chaneroid, and undulant fever.

PARLIAMENT AND STATE MEDICINE

Dr F E FREMANTLE, M P, on taking the chair of the Section of Epidemiology and State Medicine at the house of the Royal Society of Medicine on October 26th, delivered in address on "The authority of Parliament in relation to epidemic disease," but actually he took a much wider range than was suggested in the title. The common idea of Parliament as a godmother, fairy or otherwise, who did everything for her protégés was, said Dr Fremantle, fairly widespread, though it was not one that those familiar with the progress of State medicine would hold. In fact, the development of interest in questions of health, as well as in other questions, had not been from the centre to the localities, but from the localities to the centre. Such control, of a public health kind, as existed in earlier centuries arose gradually under magistrates and borough corporations—witness the regulations governing offensive trades, disposal of street refuse, and pollution of rivers. Enterprises associated more or less directly with health, such as waterworks, were started, not as the result of any central or parliamentary stimulus, but as municipal undertakings, or, as in the case of the bringing of the New River to London by Hugh Myddelton, as the result of private munificence. Parliament in the past had taken very little note of epidemics unless it had happened to be frightened by them. In the fourteenth century Parliament was even prorogued for a time, and later prorogued *sine die*, because the approach to Westminster was too perilous on account of the plague. Many public works which later came to have an important health aspect were originally undertaken for quite other reasons. The first Sewers Commission Act, in the reign of Henry VIII, was passed, not with the object of draining refuse, but as a provision against floods. The presence of decimating disease, or famine, or riot was commonly the spur to parliamentary action. The growth of public health organization the speaker compared to the growth of a tree. It had no mechanical robot-like constitution. It was a living organism, growing upwards, pruned on this side and that, but always showing fresh growth. Legislation had proceeded *ad hoc*, without system. In recent times, for example, the Midwives Act had placed midwives, not under any central health authority, but under the Privy Council. The school health system was handed over to the Board of Education. The National Health Insurance Act, with its great preventive ideal, and its special attack on tuberculosis, was the occasion for setting up completely new machinery, independent of the local sanitary authorities and the county councils. Tuberculosis orders relating to milk were within the province of the Ministry of Agriculture. Research was under the Privy Council. The War Office, Admiralty, and India Office had their medical services apart from the Ministry of Health. The Home Office was concerned with health in factories, the Board of Trade with safety in mines, and innumerable other instances could be cited. This was done deliberately because it was considered more efficient to spread health responsibility over as wide an area as possible. At the same time, an effective liaison was very necessary. Coming to a description of parliamentary procedure, Dr Fremantle reminded the meeting that the House of Lords, or at least the forty or fifty peers who habitually attended, while not a representative body, made an excellent revising chamber, and also initiated useful legislation. The House of Commons, in theory representative, included by chance those who were expert on most subjects. Among its members were thirteen medical men, five of whom were general practitioners. In Parliament they represented, not the profession but their several constituencies, though occasionally the utterances of one or other of them were quoted in the press as the opinion of the profession. With

regard to Government bills, during the drafting stage the Minister was prepared to receive suggestions from many quarters and to meet objections, but after the second reading stage it was very difficult to secure the insertion of any important amendment. The revision in committee, however, was quite a real one. The private member helped to focus opinion inside and outside the House of Commons, but, of course, party discipline was very complete, which meant that criticism was difficult. Occasionally a *measuro* was left to the free vote of the House, as in the case of the recent Edinburgh Corporation Bill dealing with venereal disease, on which the medical members were sharply divided. Most public health bills did not have to run such a gauntlet, their fate was decided in the local legislation committee upstairs. Private members' bills seldom got through, unless they were on small points, owing to the pressure on parliamentary time, but the Government departments were often glad to make use of legislation originally promoted by a private member. Even if the private member's bill did not get far, it was a useful means of ventilating matters which might later be the subject of statutory enactment. The private member had a good deal of influence at question time. Questions in Parliament, said Dr Fremantle, might be asked with the object of obtaining and broadcasting information, of airing grievances, of checking national or local administration, or of advertising the member putting the question. One of the most eminent of civil servants, now retired, had told him that he hated questions, but they were positively the only thing which kept the civil service up to the mark. Finally, Dr Fremantle voiced the need for an authoritative body of medical opinion to which members of Parliament, medical or otherwise, could refer.

RECENT EPIDEMICS OF DENGUE

THE wildfire spread of dengue has long been recognized as one of its characteristic features, and perhaps the most dramatic exhibition on record of this faculty has been presented in Greece this autumn, in Athens alone 239,000 cases occurred in the first month, with over 400 deaths. The outbreak became a news item in the daily press, and is discussed in an article in the League of Nations monthly epidemiological report for September. Dengue was unusually widespread in Colombo and in Durban in 1926, and it seems to be suggested that the disease may have extended from there to Greece. Whether this is so or not, there was no lack of dengue on both sides of the Mediterranean in 1927. Indeed, Greece itself experienced in that year something worse than is conveyed by the sentence in the report: "It appears that dengue has been present in Athens since September, 1927." In actual fact the epidemic of that year in Greece involved 20,000 cases, and was the subject of a report to the Office International d'Hygiène Publique.¹ Tunis was sharply infected in August, 1927, one-fourth of the population being affected by the disease in mild form, there was also a mild but widespread infection in Spain (Andalusia). Cases also occurred in 1927, according to the League's report, in Algiers, Syria, and Palestine. These may have been more numerous than is generally realized, for the Egyptian occurrences in 1927 are dismissed by the report in the words, "there were cases also in Egypt," though Kamal² reported epidemic dengue in Cairo with thirty to forty daily admissions to hospital, "while thousands of patients were attacked in the town." It is noteworthy, too, that many of the Cairo patients were seriously ill. Apparently dengue has been occurring in localized epidemics in French tropical Africa. Legendre³

¹ Copanaris P. Sur le récente épidémie de dengue en Grèce. *Bulletin Office International d'Hygiène Publique* 1928 vol 20 p 899.

² Kamal H. The 1927 Epidemic of Dengue in Egypt. *British Medical Journal* 1928 June 30th p 1104.

³ Legendre J. La dengue ouest africaine. *Presse Médicale* 1926 (2), p 1012.

speaks of dengue as an indigenous disease of French West Africa, "hitherto insufficiently appreciated, not confined to the Haute-Volta district, and breaking out each year in more or less epidemic form according to the number of susceptibles." Schmonilo⁴ confirms this for the French Sudan. Apparently, too, dengue has been occurring in the French Congo, where prominence of the rash and lack of the characteristic pains caused Lefrou⁵ to revive the old name *fièvre rouge*. It is interesting to note that in the Spanish outbreak of 1927 the character of the rash at first suggested some new disease, and in one account of the epidemic the disease is called "colorado," which used to be applied to dengue in Spanish America. The 1928 epidemic in Greece has been characterized by an unusual severity of the clinical features, nervous symptoms have been prominent, and encephalitic and psychical phenomena have occurred. Localized oedema and red patches have signalized local involvement of the peripheral vasomotor system. Jaundice, common in 1927, has been rare in 1928. Many of the more serious features noted in Greece in 1928 seem to have been seen, but less frequently, in the Cairo epidemic of 1927. The deaths in Greece have been mainly among the aged and invalid. As a result of this epidemic far-reaching sanitary measures are being adopted there. It is easy to believe that nothing short of such a dramatic outbreak could bring about such measures in that country, and Greece may count itself fortunate that it was not visited by one of the death-dealing pestilences.

THE AMERICAN COLLEGE OF SURGEONS

We publish elsewhere a short account of the recent meeting in Boston of the American College of Surgeons. In his presidential address on October 12th Dr. Franklin H. Martin of Chicago, one of the founders of the College in 1913, gave an account of its history, aims, and accomplishment. That the American College resembles its British and Irish forebears only in name was brought out by Dr. Martin when he said that after studying the methods of our Colleges he and his friends decided that there was no reason why they "should begin by adapting obsolete plans to a twentieth century programme," as the requirements and tests of the Royal Colleges "were formulated before modern surgery came into existence," and were similar to those applied in America to candidates for resident surgical posts in hospitals. Therefore it was determined to exact the following qualifications for the F.A.C.S. Graduation from an "A Class" medical college, one year's service as intern (house-surgeon), and two as surgical assistant, five to eight years' special training, moral and ethical fitness, specialization (that is, his practice must be 85 per cent surgical in cities of over 50,000 inhabitants and 50 per cent in smaller communities). Not only all these proofs of fitness are required, but the candidate must "file with a committee of competent surgical specialists a sufficient number of case records of major operations which he has performed himself" as a test of his all-round fitness. "These records are carefully scrutinized by a committee of practical surgeons—teachers in the four A Class medical schools of Chicago." From 25 to 51 per cent of the records are not accepted as sufficient. Several features of this institution and its organization will strike the European reader. In the first place they show how far America has departed from the former custom of allowing every man to practise any calling he likes, without test or licence, at his own sweet will. Secondly, it seems to us that there is too much talk of standardization of hospitals and of surgery. The object of the College is stated to be "to standardize the practice of surgery."

Unless the word "standardize" is used in a different sense in the United States from what is generally accepted here, we fear that such standardization is likely to come perilously near to stagnation. Thirdly, these regulations, whether so intended or not, may have a tendency to segregate operating surgeons from the rest of the profession, and to make it impossible for a general practitioner to take up surgery on an equality with the Fellows of the College, who will alone be considered eligible for surgical hospital appointments. As regards the ethical rules and the condemnation of the offence of fee-splitting, to which prominence is given, while wholeheartedly condemning this practice it occurs to us that there is here some overlapping of the field covered by the American Medical Association, which has already done so much to raise professional standards in the United States.

PHYSICAL EDUCATION IN SWEDEN

POLITICAL philosophers from time to time remind us of the great debt the world owes to the smaller nations, and the history of Europe is rich in examples of the way in which they have contributed to the advancement of science, art, philosophy, and civilization generally. It appears that in what may be called the positive side of public health Sweden has much to teach us, as was shown in a public lecture given by Mr. Torben Grut, architect to the Swedish royal family and of the Swedish Royal Office of Public Buildings, under the auspices of the Chadwick Trust, at the Royal Institute of British Architects, on October 25th. Mr. Grut's lecture fell into two main parts—the first relating to the Swedish town-planning law, and the second to the design of buildings for gymnasiums and physical training generally. The town-planning powers exercised by the provincial Governments in Sweden under the law of 1926 are evidently wider than those held by local authorities in this country. Before any area can be used for building purposes a town-planning scheme must be approved by a local board, assisted by professional advisers. Sanction may be refused for the use of unrecuttable ground, while the building regulations govern not only matters of sanitation and construction, but also the disposition and height of buildings in a scheme. Mr. Grut stated that a great improvement had already resulted from these measures, and there is no doubt that the universal application of such a method of control over building would be of considerable value in Great Britain as a means of preventing disorderly development on the fringes of the towns and the desecration of the countryside by indiscriminate building. Whether the adoption of adequate legislation is practical politics or not is another question. The lecturer, after discussing the town-planning law, devoted himself to the question of physical education—a topic which one readily associates with Sweden and with the name of Ling. He explained that the close confinement of school children in winter in an atmosphere overheated by the use of central heating had created a demand for the reform of physical education and for the appointment of highly trained games masters, charged with the supervision of the general welfare of their pupils as well as with the preservation of their health. The old Central Gymnastic Institute, founded by Ling, is accordingly being transformed into a university of physical education, which is to be housed in a new building designed by Mr. Grut. Numerous lantern slides of his plans and drawings for this structure, and for other buildings—gymnasiums, stadiums, covered tennis courts, covered swimming pools, etc.—were shown, and explained by the lecturer. Many of his designs have been prepared as standard patterns to suit the needs of towns of varying size, while all are characterized by fitness to purpose and economical construction. Perhaps the most striking feature of the lecture was not, however, the abundance of details

⁴ Schmonilo S. Au sujet de la dengue au Sudan. *Bulletin de la Société Path. Exot.* 1928, vol. 21, p. 577.
⁵ Lefrou G. Pseudo-dengue ou fièvre rouge congolaise. *ibid.* 1927, vol. 20, p. 779.

of interest in it, but the significance of what it implied. In Great Britain the use of the term "public health buildings" would signify, to most people hospitals, dispensaries, clinics, or, possibly, administrative offices. Mr. Guet took it to mean buildings for physical training and games. There is underlying this difference, perhaps, an unintended criticism of the passive conception of health so common in this country, and so opposed to the "sanitary idea" which inspired the lifework of Sir Edwin Chadwick. If he were alive to-day Chadwick would have found in the Swedish view of public health something positive and creative—a reflection of his own faith—and it is salutary to be reminded that even the most complete system of preventive medicine is only one part of Hygiene whose ultimate aim must be to raise the standard of fitness for the individual and to improve the physique of the community as a whole.

INTRADERMAL TEST FOR TUBERCULOSIS IN CATTLE

THE Tuberculin Committee of the Medical Research Council has recently issued a report¹ on a modified intradermal test devised in 1925 to replace the subcutaneous test, which though subject to fallacies and difficulties of interpretation, has hitherto been generally employed in testing cattle for tuberculosis. This modified test involves two injections of tuberculin—a "sensitizing" dose and a "reacting" dose—on different occasions, and subsequent observation of the size and certain clinical features of the resultant swelling. Professor J. Basil Buxton, F.R.C.V.S., and Dr. A. Salusbury MacNalty, the authors of the report, were appointed in 1927 to collect the views and experience of those veterinary surgeons who were known to be using the test in various parts of Great Britain. They accordingly sent a detailed questionnaire to one hundred veterinary surgeons, and the report consists mainly of a critical analysis of the replies (seventy-seven in number) they received. The general conclusion is that the vast majority of veterinary surgeons who have experience of the double intradermal test regard it as much more trustworthy in its results and much easier to conduct than the subcutaneous test. They find that the test can be readily performed under farm conditions, that its technique is easily acquired, that it has little or no effect upon milk yield, and that it may be applied without risk to pregnant cows and to young animals. This view as to its value has been repeatedly confirmed by necropsy. The general opinion, moreover, is that the ophthalmic test is unreliable, and the Tuberculin Committee suggests, therefore, that its use in conjunction with the double intradermal test should no longer be prescribed but left to the discretion of the veterinary surgeon. The report concludes with a detailed account of the method of carrying out the double intradermal test and an appendix on the potency of tuberculin.

DYSPEPSIA IN CHILDHOOD

THE dyspepsias after the age of infancy are notoriously difficult to diagnose, often masquerading as other diseases. At a meeting of the Children's Section of the Royal Society of Medicine on October 26th, Professor Jules Taillens of Lausanne dealt with this subject, of which he has made a special study for the past ten years. He pointed out that children do not complain of symptoms of indigestion until about 10 years of age, so that dyspepsia might pass almost unnoticed unless observers were on the look out for it. Dyspepsia especially in its severe forms, was apt to be very misleading for emaciation, general poor condition, fever and often cough were frequently present and led

to the erroneous diagnosis of tuberculosis. Dyspepsia in childhood was also a purely functional complaint without any serious organic lesion, and hence complete cure was much easier than in the case of adults as long as a correct diagnosis was made and the proper treatment carried out. Professor Taillens emphasized that although the digestive processes consisted of several separate actions, yet they were dependent on each other, and hence most digestive troubles begin with disorders in the stomach. Examination of over 200 recent cases showed that three-quarters of them had hyperchlorhydria. For the investigation of this Professor Taillens used a simple test meal, the ingredients of which varied with the age of the child, but were always as like a normal meal as possible. This was withdrawn about one to one and a half hours after the meal, and the free and combined hydrochloric acid were estimated. Long experience had shown him that the total hydrochloric acid in normal children was never more than 0.2 per cent, but in some of the cases of dyspepsia he found figures as high as 0.5 or even 0.6 per cent. In the treatment of these cases attention to diet was important. Professor Taillens allowed a "white diet," consisting of milk, farinaceous food, egg, white meat after the age of 5, biscuits, but no bread. The child was made to rest, with the application of heat to the abdomen. Alkalis were administered in the form of sodium bicarbonate after meals, and in bad cases a special preparation of aluminium hydrate was given before meals. Under this treatment rapid improvement could be expected with a big gain in weight, and a stay of only a few weeks in hospital would produce a cure, as evidenced by repeated regular examinations afterwards.

BRITISH COMMITTEE ON RHEUMATISM

SINCE its formation some three years ago the British Committee on Rheumatism has been a committee of the International Society of Medical Hydrology. We are informed that a meeting to consider the reorganization of this committee on a wider and more permanent basis, and as an independent body, will be held at the house of the Royal Society of Medicine, 1, Wimpole Street, W.1, on Wednesday next, November 7th, at 5 p.m. It is hoped in this manner to correlate and to guide with greater success the various efforts now being made in the campaign against rheumatism, especially as regards methods of investigation and methods of treatment and the selection and classification of cases. Any member of the medical profession who is interested in this proposal is invited to attend the meeting.

ENCROACHMENTS ON PRIVATE PRACTICE

THE opening pages of the *Supplement* this week contain the full text of a report on encroachments upon the sphere of private practice by the activities of local authorities. This important document is submitted to the Divisions, by order of the Council of the British Medical Association, in the hope that they will give it early and careful study, and forward their comments by January 5th next. The report will be considered by the Council in the light of these comments at its February meeting, and as then amended will be presented to the Annual Representative Meeting at Manchester in July. The long appendix to this memorandum will repay careful study. It consists of an account by the Medical Secretary, Dr. Alfred Cox, of his investigation at first hand into the working of maternity and child welfare centres and school clinics in certain areas.

WE much regret to announce the death in the hunting field of Dr. Louis Cassidy, Master of the Coombe Hospital and gynaecologist to the Royal City of Dublin Hospital.

Proba et Vetera.

DR BENJAMIN RUSH

At a time when the medical profession has been paying a special tribute to the memory of John Hunter it is meet and just to call to mind what manner of men were his contemporaries. Giants there were, though of lesser stature than the master himself, and as not least among them should be reckoned Dr Benjamin Rush of Philadelphia.

Benjamin Rush was born in 1745 on a farm a few miles from that city, and was educated at Princeton, where he graduated A.B. in 1769. He then commenced the study of medicine, being apprenticed to Dr John Redman of Philadelphia, with whom he worked during the following six years. In 1766 he went to Edinburgh to complete his education, and received the M.D. degree there in 1768. He returned home next year, and though only 24 years of age was at once appointed professor of chemistry in the university of his native city. During the War of Independence he served as surgeon-general of the Middle Department of the Continental Army, and was one of the signatories of the Declaration of Independence. In 1791 he was elected to the chair of the Institutes of Medicine, and six years later attended Washington during his last illness. Rush himself died in 1813. He had a very extensive practice, being credited with attending and prescribing for one hundred patients in a single day.

Rush's lectures attracted large numbers of students, and he managed to find time to write on a variety of subjects connected with medicine and the allied sciences. Most of his original papers were collected into four volumes, entitled *Medical Enquiries and Observations*. There is quite a modern flavour about the titles of some, such as

"An account of the cure of several diseases by the extraction of decayed teeth," and "An account of the influenza as it appeared in Philadelphia in the autumn of 1789, in the spring of 1790, and in the winter of 1791." "An enquiry into the cause and cure of sore legs" is peculiarly topical in view of the investigation into varicose ulceration recently set on foot by the Science Committee of the British Medical Association. In an essay on "The cause of animal life" there occurs the following observation: "The effusions even of the imagination of such men as Mr Hunter are entitled to respect. They often become the germs of future discoveries." This is a striking testimony to the wisdom of the author, while, incidentally, it shows how closely the master's work was being followed in America even in those days of strained political relations.

From the point of view of general interest an address delivered in February, 1789, entitled "Observations on the duties of a physician and the methods of improving medicine," illustrates best both the character and outlook of this wise physician. The subject no less than the author's method of dealing with it is sufficient excuse for recalling it in some detail. He begins by advising such of his audience as intend to settle in the country to establish themselves on farms for the following reasons:

It will reconcile the country people to the liberality and dignity of your profession by showing them that you assume no superiority over them from your education. This will prevent envy and render you acceptable to your patients as men as well as physicians.

The resources of a farm will create such an independence as will enable you to practise with more dignity and at the same time screen you from the trouble of performing unnecessary services to your patients and will prevent your cherishing for a moment an impious wish for the prevalence of sickness in your neighbourhood. Avoid singularities of every kind in your manners, dress and general conduct. The profane and indecate combination of extravagant ideas improperly called Wit, and the formal and pompous manner should be all avoided as incompatible with the simplicity of science and the real dignity of physic.

Let me advise you in your visits to the sick never to appear in a hurry nor to talk of indifferent matters before you have made the necessary enquiries into the symptoms of your patient's disease. Avoid making light of any case; this consideration should make you anxious and punctual in your attendance upon every acute disease and keep you from risking your reputation by an improper or hasty prognosis. Do not condemn or oppose unnecessarily the simple prescriptions of your patients. Yield to them

in matters of little consequence but maintain an inflexible authority over them in matters that are essential to life.

Preserve upon all occasions a composed or cheerful countenance in the room of your patients, and inspire as much hope of a recovery as you can, consistent with the truth, especially in acute diseases. The extent of the influence of the will over the human body has not yet been fully ascertained. Make it a rule never to be angry at anything a sick man says or does to you. Sickness often adds to the natural irritability of the temper.

You will find it difficult to attach your patients to you by the obligations of friendship or gratitude. You will sometimes have the mortification of being deserted by those patients who owe most to your skill and humanity.

We should make our charges as moderate as possible and conform them to the following state of things. Avoid measuring your services by scruples, drachms, and ounces. It is an illiberal mode of charging. On the contrary, let the number and time of your visits, the nature of your patient's disease, and his rank in family or society determine the figures in your accounts. It is just to demand more for risking your life by visiting a patient in a contagious fever than for curing a pleurisy. If a rich man demand more frequent visits than are necessary and if he impose the restraints of keeping to hours, by calling in other physicians to consult with you upon every trifling occasion, it will be just to make him pay accordingly for it. I shall only remark further upon this subject that the sooner you send in your accounts after your patients recover the better.

Give me leave to recommend you to open all the dead bodies you can without doing violence to the feelings of your patients or the prejudices of the common people. Permit me to recommend to you further the study of the Anatomy (if I may be allowed the expression) of the human mind called metaphysics.

Let me remind you that improvement in medicine is not to be derived only from colleges and universities, those facts which constitute real knowledge are to be met with in every walk of life. Let me advise you to converse with nurses and old women. They will often suggest facts in the history and cure of diseases which have escaped the most sagacious observers of nature. There is yet one more means of information in medicine which should not be neglected, and that is to converse with persons who have recovered from indispositions without the aid of physicians. Examine the strength and exertions of nature in these cases and mark the plain and home-made remedy to which they ascribe their recovery.

Steady simplicity in the preparation of your medicines by using medicines in a simple state you will obtain an exact knowledge of their virtues and doses and thereby be able to decide upon the numerous and contradictory accounts which exist in our books of the character of the same medicines. Avoid sacrificing too much to the taste of your patients in the preparation of your medicines.

With a few amendments here and there to bring it into line with present-day knowledge and practice this address by Dr Benjamin Rush in 1789 would serve equally well at a prize-giving in 1929.

ROYAL MEDICAL BENEVOLENT FUND

SUBSCRIBERS and donors to the Royal Medical Benevolent Fund are asked to forward their subscriptions for the current year before December 31st, any subscription received after that date will not appear in the yearbook of 1928, but will be included in the accounts for 1929.

At the last meeting of the committee fifty applications for grants were considered and £839 was voted to forty-seven cases. Not only the activities of the Fund, but the amount of help given, has to be restricted according to the subscriptions received. In view of the many sad cases where help is greatly needed, particularly during the winter months, an urgent appeal is made for contributions. Cheques should be sent to the Honorary Treasurer, 11, Chandos Street, Cavendish Square, W.1. The following short notes on three of the cases assisted at the last meeting show how great is the need of help.

M.B. aged 75. Following an operation had a cerebral haemorrhage and has been bedridden for 6 years. His sister is entirely dependent on him. Some of his rooms have been let and it is hoped will bring in an income of £120 a year if the tenants remain. Voted £40 to help over the present time of difficulty.

L.R.C.P. aged 79 married. Owing to age had to retire in 1922. Capital in now exhausted. His wife worked as a visiting nurse to make a living for both her earnings being the only income. She is now suffering from tuberculosis and is unable to support her husband. Voted £40.

Widow aged 59 of L.R.C.P. Completely destitute. She struggled for an existence doing envelope addressing but has now completely broken down. Her eyesight is affected and she is unable to do anything. Fund granted £25 and the Guild £25.

The Royal Medical Benevolent Fund Guild still receives many applications for clothing, especially for coats and skirts for ladies and girls holding secretarial posts and suits for working boys. The Guild appeals for second hand clothes and household articles. The gifts should be sent to the Secretary of the Guild, 58, Great Marlborough Street, W.1.

THE MATERNITY SERVICE AND LOCAL AUTHORITIES

ADDRESS BY THE MINISTER OF HEALTH

MANY hundreds of women, representing societies and municipal organizations concerned with work amongst mothers and infants, assembled at the Central Hall, Westminster, on October 30th, for a conference on maternal mortality. The meeting was a sequel to a similar conference held on February 28th last (*British Medical Journal*, March 3rd, p 368), at which a resolution was carried recommending certain lines of investigation and action with a view to reducing the high death rate of mothers in childbirth. This further conference was called principally with the object of reporting on the steps taken in this direction during the interval. The body summoning the conference was the Maternal Mortality Committee, a voluntary organization (not to be confused with the departmental committee), of which Mrs H J Tennant is chairman, and Miss Gertrude Tuokwell honorary secretary.

Mr NEVILLE CHAMBERLAIN, the Minister of Health, who was accompanied by Sir George Newman, attended, and delivered an address. After some general observations on the melancholy fact that the lives of 3,000 women every year in this country should be sacrificed in childbirth, he exhorted the gathering to "patience and courage"—a phrase which evoked some sharp comments from his feminine critics afterwards—in view of the inquiries now proceeding. The attack on this problem, he said, presented two aspects. It was necessary, first of all, to stimulate local authorities and others responsible in order that the necessary assistance might be available for these women, and then to educate public opinion so that those who needed assistance might take timely advantage of it. He expressed the indebtedness of his department to the British Medical Association for its assistance in the inquiry into maternal deaths and all cases of puerperal fever—an inquiry which local authorities have recently been urged to make. The information obtained in this inquiry, which was being considered by the departmental committee on maternal mortality, over which Sir George Newman presided, was being kept entirely private, neither the name of the patient nor of the doctor or midwife in any case being divulged. Further inquiry was also being made, again by a departmental committee, presided over by Sir Robert Belam, into the training of midwives and the conditions of the midwifery service. Mr Chamberlain then invited the criticism of his audience in a reference to the action of the Ministry with regard to the supply of milk for maternity and child welfare centres. He explained that all that he had done was to intimate to certain authorities—distressed areas excepted—that the Exchequer contribution for this purpose must not exceed a certain amount. If more milk was needed there was no reason why it should not be provided out of the ordinary local revenue, but after the prolonged industrial disturbance of 1926, which seriously reduced the national revenue, some reduction must be made even in such useful expenditures. Passing on to the suggestion that the Insurance Act should be amended so as to provide for mothers medical assistance and midwifery service before and after childbirth, he said that he thought there was general agreement that the present system, under which maternity benefit was given in a lump sum in cash, was not the best that could be devised. But the problem was difficult, as the Royal Commission realized, and for the moment he thought the only chance of progress was for some of the societies with better-off members to devise a scheme of their own. Mr Chamberlain closed with a word of reassurance about the effect on voluntary associations, particularly those dealing with the unmarried mother, of impending local government legislation. While these associations would be supervised by the councils of counties and county boroughs, nobody need be afraid that the contributions were going to be stinted or that the hold of the Ministry would be relaxed.

Dr C E S FLEMING addressed the conference on the causes for the maintenance of the high mortality rate. He was inclined to think that there was not much wrong anywhere in midwifery practice, but that there was something

wrong everywhere. Mortality and morbidity attending childbirth had been for too long taken for granted. Many patients demanded intervention with a view to quick and easy labour, and it was difficult for the doctor—more difficult for him than for the midwife—to resist such importunities. Sufficient attention had not been paid to the fact that the labour was only one phase of the process, and ante-natal and post-natal care was necessary. There had also been an inadequate appreciation of the value and position of the midwife in the service. The division of work between doctor and midwife was not quite so easy as it might appear, and until there was a sufficient supply of thoroughly qualified midwives there would have to be some system of supervision by the medical man in ante-natal work, but care must be taken that such supervision did not interfere with the responsibility of the midwife, because that might react on her carefulness.

Dr MARION PHILLIPS presented a report on the action taken since the last conference in February. The most interesting part of this report was the result of an inquiry into the adequacy of the maternity services in the areas of the local authorities. Out of 48 counties, returns had been received from 42, and out of 79 county boroughs, from 74. Although some of the returns are indefinite and certain assumptions have had to be made, the results may be usefully set out in tabular form.

	County Councils (42)	County Borough Councils (74)
Employ health visitors	All	All
Have ante-natal clinics	32	68
Provide subsidies to enable midwives to practise in districts which otherwise could not support them	13	4
Pay part-fees to midwives when patients cannot afford full fees	9	Not ascertained
Provide beds for patients whose home circumstances are unsuitable	31	68
Reserve beds for ante-natal observation	14	48
Reserve beds for treatment of puerperal sepsis	22	57 (9)
Provide milk or food during part of pregnancy and lactation	23	72
Pay fees of doctors called in emergency	All	All
Pay consultants fees in complicated cases or puerperal infection	16	37
Provide skilled nursing for patients confined at home	17	32
Provide convalescent home treatment after confinement	12	Indefinite
Assist unmarried mothers	19	22

Roughly it appeared, said Dr Phillips, that about 16 county councils and 45 county borough councils were aiding the maternity service of the district by putting into force half or more of the provisions for which a grant in aid could be obtained. It was noteworthy that it was not the richest areas which were, in general, doing most.

When the meeting was thrown open for general discussion, many speakers, including several who were described as women aldermen or councillors, criticized the Minister for his action in connexion with the milk supply, and also, as they alleged, for holding up schemes for clinics or maternity homes. The question of birth control also raised its head, and Mrs BERTRAND RUSSELL gave some figures as to the increase of the miscarriage rate in Germany (where miscarriages were notifiable) from 5-10 per cent of all pregnancies in 1909 to 40-50 per cent in 1926. She said that it was impossible to believe other than that this was in response to the practice of artificial abortion by desperate women. No inquiry into the whole question of maternal mortality could be blind to the alternatives either of legalizing abortion or of providing proper contraceptive measures at clinics—a statement which was received with loud applause from a section of the conference and no audible dissent.

A resolution was carried welcoming the appointment of the two departmental committees and the co-operation of the British Medical Association in these steps and its interest in the better training of medical students in midwifery, noting also with regret the inadequacy of the maternity services in many parts of the country.

EIGHTEENTH ANNUAL CONGRESS OF THE AMERICAN COLLEGE OF SURGEONS

[FROM A CORRESPONDENT]

THE eighteenth annual congress of the American College of Surgeons took place in Boston, Massachusetts, from October 8th to 12th. As usual, it was well attended, there being present 2,500 delegates and several prominent foreign guests. This meeting was especially worthy of note for the reason that its chief founder and director-general, Dr. Franklin H. Martin of Chicago, was its president for the ensuing year.

At the opening meeting, held on the evening of October 8th, an address of welcome was given by Dr. Fredric J. Cotton (Boston), chairman of the Committee on Arrangements. Dr. George D. Stewart (New York), the retiring president, gave an address, after which the foreign guests were introduced. These were Dr. Daniel J. Cranwell (Buenos Aires), Sir Charles P. B. Clubbe and Sir George A. Syme (Australia), Sir Charles Ballance, Mr. T. P. Dunhill, Sir Squire Sprigge, Mr. George E. Waugh (London), Dr. Percy T. Hughes (Bromsgrove, Worcestershire), Dr. T. de Martel (Paris), the late Dr. Louis Cassidy and Dr. Charles J. McAuley (Dublin), Professor Vittorio Putti (Bologna), Drs. Rafael Reygadas and Ulises Valdes (Mexico City), Mr. Charles G. F. Morice (New Zealand), Dr. Farquhar Macrae and Professor Archibald Young (Glasgow), and Sir John Lynn Thomas (Llechryd, Wales). In his inaugural address as president, on "The evolution of clinical medicine and surgery in relation to the preservation of health and life," Dr. Franklin H. Martin indicated that the next step in the direction of preserving health would be a campaign against the degenerative diseases. Problems of disease, one after another, had been and were being conquered, and not only the trained physician had this knowledge, but the educated layman too was prepared to accept preventive and curative scientific medicine as the recognized authority, and to submit himself to periodical medical examination.

The John B. Murphy Oration, on "Malignant bone tumours," was given by Dr. Vittorio Putti of Bologna, who began by remarking that surgical intervention was still the sheet anchor in treatment of malignant bone tumours. Uncertainty in diagnosis, hesitation on the part of the patient, reluctance of the surgeon to undertake a mutilating operation, inevitable and almost always useless attempts to make a conservative cure, were the causes of loss of precious time, and took from the radical operation most of its chances of success. Dr. Putti insisted that the crux of the problem was the difficulty in differentiating between the malignant and benign bone tumour in the stage early enough for operation to be effective. He expressed the hope that the treatment of bone sarcoma by x-rays had not yet reached its limit.

On this evening of October 8th Sir Squire Sprigge delivered the Huntean Oration, entitled "Grand curiosity, before a very large audience." He suggested that John Hunter's lack of education as a boy, with an intensive training as a young man, was the best he could have received in view of the work that he was to do. The ruling passion of his life was a curiosity which would not be satisfied until he had probed as deeply as possible into every problem. The orator drew an interesting comparison between the lifework of John Hunter and Harvey and between that of Lister and Hunter, and the leading theme that ran throughout the address was that John Hunter's obsession of insatiable curiosity, directed by a master mind, was the driving force which made of him the greatest and most original conformational anatomist the world had ever seen. On the same evening a symposium on arterial transplantation was held. Dr. Robert C. Coffey (Portland, Oregon), the pioneer of the method, read a paper on transplantation of arteries into the large bowel. Dr. Arthur H. Curtis (Chicago) discussed the same subject, and Dr. Charles H. Mayo (Rochester, Minnesota) spoke on contributing causes of genito-urinary anomalies.

On the evening of October 10th a special meeting of the Boston Surgical Society was held for the purpose of presenting the Henry James Bigelow medal to Dr. Chevalier Jackson of Philadelphia. This medal is given in recognition of great proficiency in surgery. Dr. William P. Graves, vice president of the society, gave an introductory address, and Dr. Harvey Cushing presented the medal. Before the medal was awarded Dr. Jackson gave an illustrated lecture on bronchoscopy, its history, methods, and benefits to mankind. A long series of pictures were shown in which were depicted the extraordinary range of articles capable of being inspired the commonest object in the case of infants being the safety pin. Dr. Jackson described how the bronchoscope could now be introduced as far as the diaphragm and manipulated dexterously, so that the

operator could often draw out the impacted or entangled safety pin, piece of jewellery, or what not. Especial attention was directed to the danger of infants swallowing peanuts, which have a peculiarly irritating action upon the mucosa, exciting violent inflammation, with a very considerable rise of temperature. Prohibition had had a significant effect upon the practice of bronchoscopy. When drunkenness was much more prevalent than at the present time it was no infrequent occurrence for an inebriated person to bolt large lumps of food requiring instant removal by mechanical means. The address and demonstrations left no doubt of the great value in skilled hands of bronchoscopic methods for removing foreign bodies introduced by way of the mouth. The speaker claimed that bronchoscopy was a useful aid to diagnosis in the detection of malignant diseases in certain situations.

On the evening of October 11th papers were read by Professor Archibald Young on sacro-coccygeal chordoma, by Sir Charles Ballance, on the International Cancer Conference and British Empire Cancer Campaign, by Dr. George Crile on the adrenaline factor in hyperthyroidism, while Sir John Lynn Thomas showed motion pictures on orthopaedic subjects.

On the evening of October 12th the convocation ceremonies took place. First, honorary Fellowships were conferred upon Sir Charles Ballance, Sir John Lynn Thomas, Sir Squire Sprigge, and Sir George Syme. The candidates for Fellowship, nearly seven hundred in number, were presented, and Fellowships were conferred. The president, Dr. Franklin H. Martin, gave the presidential address, and Dr. William J. Mayo (Rochester, Minnesota) the Fellowship address.

In regard to the clinical activities of the Congress it must suffice to say that at the numerous hospitals of Boston and neighbourhood, and at the Harvard Medical School, a large programme was carried through successfully. Many symposiums were held on special surgical subjects, industrial surgery, and other matters concerned with surgery. This brief notice would, however, be incomplete without some reference to the outstanding problem which the American College of Surgeons has grappled with of late—namely, the standardization of hospitals. The College has set up a minimum standard for hospitals, and those hospitals which, in the opinion of its inspectors, do not reach this standard are not approved. At the present time it is the aim of every hospital in the United States to be approved by the College, and it has come to be regarded as a stigma on any institution for the treatment and care of the sick and injured if it fails to satisfy the College inspectors. Already, it is said, this hospital policy of the College has resulted in raising greatly the efficiency of North American hospitals, and this hope is expressed that future results will be even more satisfactory.

Surgeon General Meade W. Ireland of Washington has been elected president of this College to succeed Dr. Martin next year, and Drs. William E. Pearson (Iowa) and Perry G. Goldsmith (Toronto) have been elected vice presidents. It only remains to add that the hospitality of the members of the medical profession of Boston to their visiting brethren was unbounded, and that the organization of this meeting left nothing to be desired.

AN INTERNATIONAL INQUIRY INTO SYPHILIS

UNDER the auspices of the Health Organization of the League of Nations a meeting of experts on syphilis and cognate subjects was held at Geneva from October 8th to the 10th. The following were present: Professor Jadassohn, director of the University Skin Clinic, Breslau (chairman), Dr. T. Madsen, director of the State Serum Institute, Copenhagen, Colonel L. W. Harrison of the British Ministry of Health, London, Dr. Louis Quérat, president of the Ligue nationale française contre le Péri venérien, Paris, Dr. J. H. Stokes, professor of dermatology and syphilology in the University of Pennsylvania, Philadelphia, and chairman of the Scientific Committee on Research in Syphilis, New York.

The chairman referred to preliminary discussions between Dr. Madsen, Colonel Harrison, Professor Jadassohn, and Professor Rasch, director of the State Hospital, Copenhagen, which were held at Copenhagen on June 6th and 7th and also to matters which had been the subject of correspondence between the experts. At his proposal the following agenda was adopted:

1. Variations in the prevalence of syphilis. Methods of determining the underlying causes.

2. Prevention of syphilis. Comparative study of the experience gained by the public health agencies concerned in various countries. Proposed plan of inquiry into the effectiveness of the treatment of syphilis in selected clinics and dispensaries of several countries.

3 Miscellaneous Methods of teaching medical students the modern treatment of syphilis in the medical schools Standardization of drugs used in treatment of syphilis (work of the Permanent Standards Commission)

After discussion of these points the conclusions were summed up in the following terms

INQUIRY INTO SYPHILIS TREATMENT

The experts have been struck by the fact that, in the fight against syphilis, the results obtained have not been such as the almost universally recognized progress of syphilis therapy would give reason to expect. The explanation which suggested itself, and which has indeed been confirmed by various authorities, is that new discoveries in the matter of syphilis diagnosis and therapy are not exploited everywhere in the right way and with such promptness as would be desirable, and that a uniform generally recognized method of treatment does not exist as yet. The experts therefore considered whether a statistical compilation regarding the various methods of treatment in clinics, dispensaries, etc., would not enable a better general idea to be gained of the efficacy of these methods.

The material available at individual clinics is large enough, and has usually been treated by one, or at most, a very few methods. The attempt must therefore be made to bring together as much material as possible from different clinics in different countries to enable the various methods to be compared on the broadest possible basis. In this connexion it appeared desirable to keep in view the two purposes to which every treatment of syphilis should be directed—namely, the suppression of contagiousness as quickly and as effectively as possible, and the protection of the patient from the severe late effects of syphilis.

The experts recommend that the work be organized on the following lines. The material from the various clinics which are ready to participate would be sent to the health section acting as central bureau of this inquiry on cards relating to individual patients ('individual case record'). On the basis of the material thus received the bureau would then work up the various questions which arise in connexion with the treatment of syphilis and its results. For this purpose a large number of cards, giving as accurate particulars as possible, will be required. Directors of clinics would therefore be requested to work up their cases for a given period of years to be determined by them, and would include all cases of primary, secondary, and tertiary syphilis which have been under observation in their clinics for more than six months, and all the older cases for which adequate medical histories are available. Beyond this, however, no further selection of cases would be made. In addition to the cards, which will be filled in under his supervision, the director of each institute will also be asked to prepare a general statement of the principles which he employs, or of the various principles which he has applied at different times.

Apart from this retrospective statistical compilation, it should be suggested to those clinics which are prepared to place their material at the disposal of the Health Organization in this form, that they should start at a given date, recording all newly arriving cases of (fresh or old) syphilis on the lines of these individual cards, in order that, a few years hence, they may be in possession of records which will lend themselves without further modification to these statistical uses. It would be desirable that in the larger centres those agencies which are concerned with this matter—for instance, insurance funds, private institutions, and dispensaries—should combine for the purposes of this investigation.

PROPERTIES OF DRUGS USED IN TREATMENT OF SYPHILIS

The Committee is of opinion that it is highly regrettable that bismuth preparations which do not correspond to the manufacturers' indications should be placed on the market in various countries. It suggests that the practice, already adopted by certain countries, of official chemical testing of bismuth preparations should be made widely known, perhaps through the machinery of the Health Organization.

The Health Committee may wish to suggest to the sanitary administrations of the countries following this practice that they communicate periodically the results of the observations made to the secretariat of the League. In the view of the Committee the national studies on the biological and chemical composition of various bismuth compounds will have to be continued in the different countries before the question of an international co-ordination of any such studies may be taken into consideration.

METHODS OF TEACHING THE MODERN TREATMENT OF SYPHILIS

The Committee considers that, in view of the prophylactic importance of modern methods for the diagnosis and treatment of syphilis, no national plan of preventive measures against syphilis is complete which does not provide for theoretical and practical training of medical students in syphilology, followed by the sanction of official examination.

In the Committee's opinion the authorities should also facilitate in every way continuation courses in syphilology for general practitioners and medical officers.

In view of the complexity of the question of variations in the prevalence of syphilis the experts decided to adjourn discussion on this point to a later date.

Canada.

[FROM OUR CORRESPONDENT IN MONTREAL]

Visit of the British Medical Association in 1930

THE Annual Meeting of the British Medical Association to be held in Winnipeg in the summer of 1930 is looked forward to with great cordiality. While the Western Provinces will be the more immediate hosts, it is hoped that at least some of our visitors will take the opportunity to see something of the maritime provinces. Without this their knowledge of Canada will be, let us say, incomplete. There is an East, as well as a West, in Canada. They meet, it is true, frequently and harmoniously, but they have, and probably always will have, their distinctive features.

Resignations and Appointments.

There have been many changes in the teaching staffs of the various Canadian universities recently. The resignation of Professor A. B. Macallum from the chair of biochemistry at McGill University, after a long and brilliant career in teaching and research, has already been referred to. Professor R. F. Rutan has retired from active teaching work, after having been associated since 1886 with the teaching of chemistry at McGill, where he eventually became dean of the faculty of graduate studies. The appointment of Professor J. J. Macleod to the regius professorship of physiology in the University of Aberdeen causes a vacancy in the staff at Toronto University and his departure is keenly felt by a very wide circle. Professor H. M. Torr, who has been president of Alberta University since its foundation, has resigned to become president of the National Research Council of Canada. Professor J. B. Collip, also of Alberta University, whose name has been associated with such brilliant research on the parathyroids, has accepted the chair of biochemistry at McGill University.

A new appointment has been made in the McGill Medical Faculty in the person of Dr. Wilder Penfield, who is to take up the clinical professorship of neurological surgery. Dr. Penfield is a graduate of Princeton and Johns Hopkins, and was Beit Memorial Fellow at the National Hospital, Queen Square. Later he was assistant professor of surgery at Columbia University and attending neurologist at the Vanderbilt Clinic.

The Teaching of Medicine in British Columbia

The first stirrings of a movement for the development of a medical faculty in the University of British Columbia are making themselves felt. An editorial in the Vancouver Medical Association Bulletin asks why the medical profession in the province is allowing so many of its sons and daughters to go for their medical education to centres in Eastern Canada and the United States, and suggests that a beginning might be made by establishing a chair in some such subject as anatomy in the University of British Columbia, which could give a course fulfilling the requirements of the first two academic years in universities such as McGill and Toronto. That no opportunity may be lost to pierce the word in season another passing reference is made in a later article reviewing Dr. Hengert's recent book *Four Centuries of Medical History in Canada*. The second volume of this work deals with the origin and growth of medical education in every province in Canada except British Columbia, it is remarked that "British Columbia

is significantly blank." If, however, that province has not yet built up a medical school it is certainly not for lack of wishing to keep abreast of medical advance. The Summer School of the Vancouver Medical Association had this year the largest attendance yet recorded, there being 200 present. As teachers there were clinicians and lecturers from Montreal, Toronto, Winnipeg, and Johns Hopkins, while due attention was given to entertainment and relaxation. It would be hard to conceive a better plan for what really is a short post-graduate course. This was the eighth annual summer school, and there seems to be little doubt that others equally successful will be held in future years.

Union of South Africa.

[FROM OUR CORRESPONDENT IN CAPETOWN.]

University of Capetown New Medical School

THE second of the two blocks constituting the Wernher-Reit Laboratories of the Medical Department of the University of Capetown has recently been completed and is now in active occupation. In its main architectural features it is similar to the first block (a description of which appeared in the *British Medical Journal* of September 17th, 1927, p. 500). It lies adjacent to, and parallel with, the first block at its south-western extremity, it consists of three floors, and in shape resembles the letter E. In it are housed the departments of anatomy, physiology, and physiological chemistry.

The Department of Anatomy

The department of anatomy is in the charge of Professor V. R. Drennan, who is assisted by a staff of lecturers and technical assistants. It occupies the entire south-western half (or right wing) of the new building, comprising all three floors, which are connected by the main stairway and a large electrically driven lift. The receiving room, a commodious apartment provided with three fixed post-mortem tables and with large slate chests and earthenware troughs for the storage of wet teaching preparations, is situated on the ground floor. Adjoining the receiving room is a spacious workshop equipped with the appropriate appliances, and with a large and a small band saw for cutting sections of the hardened body. These saws and the other machinery are electrically driven by means of pulley belts operated from overhead shafts. In the receiving room the bodies are hardened, injected and prepared for dissection. Opening from the opposite end of the receiving room is the tank room, containing three large built-in slate-lined storage tanks in which the bodies are stored in the dry state. The capacity of these tanks is some fifty bodies—a more than ample supply. By a special Anatomy Act the medical school is allowed the use of bodies for six months at the expiration of which they must be coffined for burial. Material is derived from unclaimed corpses, which, in a country of immense distances like South Africa, with an overwhelming preponderance of native population are particularly numerous. So ample is the supply of material that each student is expected to dissect the human body at least twice. On the ground floor also is a dark room fitted with two fixed projection microscopes of the Edinger type for the reconstruction of models from microscopic specimens or sections, and adjacent are two photographic dark rooms suitably equipped. The remaining apartment on this floor consists of a technical assistant's room, with adjoining bone depository or library. The latter contains a series of some five hundred built-in wooden boxes for the reception of osseous specimens, each box being provided with an index card that greatly facilitates reference to particular specimens.

Dissecting Room Features

On the first floor is situated the main dissecting room for students containing sixteen marble-topped teak tables. Each table is provided with four teak stools with leather-thonged seats and is lighted by two overhead electric lamps. There are also central flood lights fixed to the ceiling. The floor is cemented and built with a camber to facilitate flushing the water being carried off by a drain at one end. A large electric geyser ensures a plentiful supply of hot water. Lockers for students are provided in the corridor just outside the dissecting room. A separate dissecting room for women students contains four tables arranged much as in the men's dissecting room, although the sexes are separated in the dissecting room both attend the same lectures and demonstrations. On the first floor there is also a laboratory for embryological research and

a room for the study of surface anatomy, this latter room is furnished with weighing scales, height measuring devices, and other anthropometric appliances. Two cubicles are provided where students may disrobe and study surface markings on each other. A locker room and a retiring room for lecturers complete the accommodation on this floor.

Anatomical Museum

The top floor contains the lecture theatre, accommodating about 120 students in ascending tiers of seats built in a semi-circular amphitheatre. Ten windows at the back and sides of the apartment provide adequate lighting. An Edinger projector for microscopic specimens is installed, and an epidiascope is to be provided later. Just outside the two entrances to the theatre are recesses, one of which contains a large chest with sliding drawers in which diagrams and charts can be filed on the flat, while the other contains storage space for bones, models, and other specimens used to illustrate the lectures. The spacious anatomy museum, also on the top floor, contains eight glass showcases centrally arranged, as well as two large glass wall cases containing anatomical models and embryological and anthropological preparations. The museum is also fitted along one side with thirty glass-topped cabinets with protecting wooden lids for the demonstration of delicate specimens without risk of damage. A card descriptive of each specimen is fixed to the inside of the wooden lid and is available for speedy reference. Adjoining the museum is a large laboratory for the study of physical anthropology, equipped with a dioptraph and other instruments for the exact measurement of specimens. Further along the corridor are two research rooms for private study, and another apartment, fitted with metal shelving for the storage of glass jar preparations. The professor's retiring room is comfortably furnished, and, with a private laboratory, completes the accommodation of this department.

The left wing of the new block is occupied by the departments of physiology and physiological chemistry. In charge of the department of physiology is Professor W. A. Jolly, dean of the medical faculty of the university, while Dr. E. Bosman is lecturer in charge of the department of physiological chemistry.

Physiological Equipment

On the ground floor of the new block are the retiring room of the professor of physiology and his private laboratory. The electro-physiology room opposite is equipped for investigating the electro-physical properties of the two strong galvanometers working on the principle of the possible to record graphically the responses of two separate organs simultaneously. The physiology museum contains large cases in which are displayed instruments used in experimental physiology and models of organs. On this floor is also a large workshop fitted with the tools necessary for the upkeep of the instruments used by the department. Here, too, new apparatus is constructed and instruments are copied. Adjoining the workshop is the battery room, containing a motor transformer for converting alternating current from the mains to direct current. Leading from the corridor is the students' histology room accommodating from forty to fifty students. It is equipped with four rows of benches, each student being furnished with a microscope, an illuminating lamp, and complete sets of reagents. Adjoining this room is a preparation room where specimens used in connexion with the class are prepared. On the ground floor is also a large laboratory or histology preparation room fitted with a fume chamber and electric and gas incubators. A plethysmograph room and a photographic dark room complete the accommodation on the ground floor.

Provision for Research

The first floor, like the ground floor, is occupied by the department of physiology, here is situated the lecture theatre, accommodating about 120 students. Armchairs replace the usual benches in order to obviate bending forward over a desk and interference with natural respiration. The right hand arm of each chair ends in a broad expansion on which the student may write while sitting erect. On this floor there is also a large experimental laboratory for students fitted with a fume chamber, an apparatus for smoking record paper, and working benches. Each student is provided with the most up-to-date type of revolving drum driven by means of overhead shafting operated by electricity. A separate experimental laboratory for advanced students contains a large kymograph and adjoins a preparation room. In addition there is a large research laboratory.

Physiological Chemistry

The top floor is occupied by the department of physiological chemistry and contains a students laboratory accommodating forty students and fitted with the necessary apparatus and reagents. A small demonstration theatre adjoins it. The dark room contains up-to-date polarimeters and calorimeters and is otherwise equipped for the work of the department. Opposite

is a research room used at present for the clinical work derived from the General Hospital. The remainder of this floor consists of a lecturers' room and private laboratory, a pathological chemistry room, a low temperature room, and a store room.

England and Wales.

The Cardiff Meeting of 1928

Winding up Reception

On the evening of October 23rd a reception and dance was held in the City Hall, Cardiff, to mark the winding up of the affairs of the Annual Meeting of the British Medical Association held in Cardiff in July last. Upwards of three hundred members and friends were present, and the official guests included the Lord Mayor and Lady Mayoress of Cardiff, Sir D. R. Llewellyn, Bt., and Lady Llewellyn, Mr. and Mrs. Allcock, and a number of others who had contributed to the success of the Cardiff meeting. The President, Sir Ewen Maclean, and Miss Maclean received the guests at 9 p.m., and dancing went on until 2 a.m. At 10.30 p.m. there was an interval, during which the company assembled in the Council Chamber and certain presentations were made to those who were particularly associated with the central organization of the work of the meeting. The Lord Mayor said that not only had it been an honour to the Association to be entertained by Cardiff, but it had been an equal honour to Cardiff to be visited by the Association, and that he and the City Council had been delighted to contribute to the success of the proceedings. Dr. W. E. Thomas, vice-chairman of the General Committee, then presented to Miss Maclean a gold bangle set in diamonds. He spoke of the appreciative accounts of the Cardiff meeting which he had heard on all sides, and pointed out that such success could not have been achieved but for the great work of the Ladies' Committee and of Miss Maclean, its chairman. Miss Maclean, in reply, expressed her great appreciation of the presentation, and paid a tribute to the work of her secretaries, Mrs. Cresswell and Mrs. Strachan, and to the officers of her various committees. Sir Ewen Maclean then presented the secretary of the Ladies' Committee, Mrs. F. P. S. Cresswell, with a jewelled wrist watch, and the general secretary, Dr. G. I. Strachan, with a gold wrist watch and a silver lamp. He referred in glowing terms to the work put in by both these officers in connexion with the Cardiff meeting, and Mrs. Cresswell and Dr. Strachan replied appropriately. The final presentation was to Mr. John Allcock, the city treasurer, who had acted as honorary treasurer of the meeting. This also was made by the President, and consisted of a clock and two bronzes. Mr. Allcock's great services as honorary treasurer were acknowledged, and in his reply Mr. Allcock said that it had been a great pleasure to assist the Association in this way. A most enjoyable evening was spent, and the function was in every way a great success.

St. Thomas's Hospital Dinner

The old students' dinner of St. Thomas's Hospital has always been a very agreeable and well attended function, and especially so on the last two occasions, when past and present members of the staff and medical school held their annual gathering in St. Thomas's House, the admirable new residential club building in Lambeth Palace Road. At this year's dinner, on October 26th, the chair was taken by Mr. E. F. White of Crowborough, past-president of the South-West London Medical Society. The large company included Sir George Makins, Sir Cuthbert Wallace, Dr. A. E. Russell, Dr. H. G. Turner, Sir Percy Sargent, Professor H. R. Dean, Mr. Samuel Osborn, Dr. J. S. Fairbairn, Dr. F. F. Caiger, Professor F. G. Parsons, and Professor Hugh MacLean. After the King's health had been honoured the chairman proposed the toast of "Prosperity to the Hospital and its Medical School," and in a reminiscent speech expressed the affection and loyalty felt for St. Thomas's by all old students. The toast was responded to by the almoner, Mr. George Roberts, on behalf of the governing body of the hospital, and by the

dean, Professor L. S. Dudgeon, on behalf of the medical school. Mr. Roberts conveyed a message of regret from the treasurer, Sir Arthur Stanley, at his enforced absence, and welcomed very cordially the recent appointment of Colonel R. J. C. Thompson, a distinguished old St. Thomas's student, as medical secretary of the school, and of Mr. A. P. B. Irwin as secretary of the hospital in succession to Mr. G. Q. Roberts. Professor Dudgeon began with a warm tribute to the enormous services rendered to the hospital and school by his predecessor in the office of dean, Sir Cuthbert Wallace. He congratulated Sir Percy Sargent on his knighthood at the New Year, and mentioned with regret the deaths of Sir Bryan Donkin, Dr. J. J. Perkins, and other prominent old students. Among the events of the past year had been the holding for the first time of a post-graduate course for old students at the close of the long vacation, and the establishment of a chair of dietetics. As in previous years, a short toast list was followed by the informal reunions which distinguish such evenings from those spent wholly in ceremonial feasting.

Care of the Feeble-minded

In an address entitled "Yesterday and to-day in mental hygiene," delivered at the Royal Albert Institution, Lancaster, on the occasion of its twelfth quinquennial festival, Sir Robert Armstrong-Jones, Lord Chancellor's Visitor in Lunacy, gave an account of the history of the movement for the care of the mentally defective in this country. The movement, he considered, began with Dr. Samuel Gaskell, who, in the course of three articles in 1847 in what was then called Chambers's *Edinburgh Journal*, gave an account of the work carried on at the Bicêtre Hospital, Paris, on behalf of the feeble-minded. These articles inspired Dr. Andrew Reed, father of Sir Charles Reed, first chairman of the London School Board, to found Park House, Highgate, one of the first homes for mental defectives in this country. This was followed in 1850 by the opening of Essex Hall, Colchester—now the Eastern Counties Institution—and of Earlswood in 1853. The wisdom and sympathy of Dr. Andrew Reed, stimulating like feelings in various eminent northern citizens, inspired the foundation of the Royal Albert Institution in Lancaster. To-day, said Sir Robert Armstrong-Jones, the supporters of the Royal Albert Institution were still animated by the spirit of Andrew Reed. They were devoting themselves to the study of human nature in its most humiliating forms, so that they might help to alleviate the distress of parents and kindle in them a hope of improvement in their afflicted children. The Royal Albert Institution, by tact, skill, and kindness, educated the untaught, the undisciplined, and the uncared-for to be helpful to themselves and to others. He believed that the transformation of character achieved in the sullen and self-willed was a testimony to the patience, interest, and skill of the medical superintendent and his staff. The outcome of the inquiries into the problem of the feeble-minded by the Royal Commission of 1904-8 was the enactment for England and Scotland of the Mental Deficiency Act of 1913, amended in 1927. This Act made three authorities—the county and borough councils, the educational authorities, and the Poor Law guardians—responsible for the feeble-minded. Sir Robert Armstrong-Jones made a plea for the continuance of the work of these authorities. This would ensure control of the feeble-minded after the age of 16, a period when they most needed and could profit from such control. He concluded by paying a warm tribute of respect and admiration to the enthusiasm of the voluntary workers who had given so much of their time to looking after those who had left school and were otherwise not cared for. Local voluntary mental welfare associations who befriended and visited mental defectives, in his view, did a great service not only to their country, but to all humanity.

Pathological Research in Leeds

In the annual report for 1927 of the department of pathology and bacteriology of Leeds University, Dr. M. J. Stewart, professor of pathology, and Dr. J. W. McLeod, Brotherton professor of bacteriology, give a gratifying account of research work completed and in progress. One

outstanding feature is the elaboration of a practical application of the oxidase reaction to bacteriological technique. This has greatly facilitated the recognition of the gonococcus, meningococcus, cholera vibrio, and other bacteria in mixed culture, and has already been brought into extensive use in the diagnosis of gonorrhoea by cultural methods. The time required for the examination is reduced by more than half, and the operation has gained considerably in accuracy. Certain theoretical aspects of the bacterial oxidase are now being explored. Study of the morbid anatomy of the stomach and intestine is continuing, two papers on tuberculosis in this region have been published, and an extensive account of gastric and duodenal ulcer is being prepared in collaboration with Dr A. F. Hurst. A large series of patients who have undergone partial gastrectomy is being followed up and a report is being prepared. Other investigations in progress relate to the determination of the presence of bile salts, the etiology of gall bladder infection, pulmonary asbestosis, tuberculosis of the tracheo-bronchial lymphatic glands and the male genito-urinary tract, myeloid epulis of the jaw, the antigenic components of *Salmonella* strains, and the diagnostic value of the fractional test meal in diseases of the stomach. The routine work of the department has considerably increased and some addition to the staff is contemplated. Plans for a new pathological institute have been prepared, and work has already begun on the extension of the main medical school buildings, which will temporarily accommodate the bacteriological section during the erection of its future home. At the request of the Leeds Board of Guardians, Professor Stewart drew up a scheme for pathological work at St. James's Hospital, and a new and well-equipped laboratory has now been opened. In addition to routine and research work a short post-graduate course in surgical pathology was given during the autumn term of 1927, and officers of the department collaborated in a post-graduate course of instruction for general practitioners. An experimental firm has been acquired by the department of experimental pathology and cancer research of which Professor R. D. Passer is director. The work in this department during the past year has included a study of the effect of physico-chemical changes on the growth of cells. As the result of an inquiry it is reported that there appears to have been no real increase recently in lung cancer and that, when due allowance has been made for the increase in the number of necropsies and the number of patients admitted to the Leeds General Infirmary, where the investigation was conducted, cancer in general does not appear to be a more frequent finding than it was thirty-five years ago.

Tuberculosis in Lancashire

The tuberculosis death rate in Lancashire has been consistently lower than that for England and Wales, and a still further decrease is announced by Dr G. Lissant Cox, central tuberculosis officer of the Lancashire County Council, in his report for the year 1927. It is noteworthy that the decline in the death rate has occurred in spite of the serious amount of unemployment in the staple industries in this county during the last five years, but Dr Cox is doubtful whether it will continue in 1928 with the industrial condition almost unchanged. The factors which appear to be concerned in this abatement of tuberculosis call for some consideration. They include special measures dealing with the disease, supervision of the home conditions of patients, with education in hygiene, isolation in hospitals, and the destruction of cows suffering from active tuberculosis. That such local measures have played a definite part is indicated by the fact that the fall in the death rate in 1927 coincided with a rise in the general death rate from all causes in Lancashire by as much as 6 per cent above that in 1926. Dr Cox discusses these measures under three headings—namely, the dispensary unit with which is included the notification of cases, the institutional unit, and the after-care of patients. He reiterates his belief that the dispensary unit should operate over an area with a population of 350,000 in urban centres, or of 250,000 in the case of rural districts, he is convinced that smaller areas tend to inefficiency. Such a unit can, he finds, be staffed adequately by one consultant

and two assistant tuberculosis officers. Moreover, it is urged again that the dispensary tuberculosis officer should have beds at his disposal; this has been arranged in the case of four out of five of the Lancashire dispensary areas. Sparsely populated rural districts may be linked to sanatoriums, in this way the medical superintendents of these institutions are prevented from being isolated and can take part in dispensary work. It is advised that sanatoriums should be kept small, 150 beds being the maximum. The value of after-care committees is emphasized, nineteen of these are at work in Lancashire. This county has paid particular attention to leprotherapy. The results of light treatment in non-pulmonary tuberculosis were very satisfactory in 1927, especially in dealing with lupus and adenitis with abscess formation and skin involvement. Research is being continued as in previous years, an annual sum of £200 being received from the Lancashire County Council for this purpose. Various forms of treatment are investigated and study is being made of the fate of young children in tuberculous households, the circumstances attending non-notification and late notification, the proportion of cases diagnosed in the first place by radiological examination and subsequently confirmed clinically, and the high prevalence of tuberculosis in the Fimess sub-area. Although silicosis is not an acute problem in Lancashire it has received attention, and evidence has been obtained that the inhalation of silica dust helps to increase the death rate from tuberculosis. Cordial co-operation of tuberculosis officers with general medical practitioners is emphasized by Dr Cox as being an essential feature of a properly co-ordinated scheme. The large majority of new patients examined by tuberculosis officers were referred in the first place by general practitioners as being suspected cases, the remainder were the result of notification. The systematic use of x-rays in the county dispensaries provides a valuable additional diagnostic procedure. Routine medical treatment which can be provided by private practitioners is not arranged at the dispensaries. Doctors commencing or taking over practices are informed by the tuberculosis officer of the address of the nearest dispensary and the facilities existing for special lines of treatment. With a view to intensifying the interest and efficiency of the staff, short post-graduate courses for tuberculosis officers and nurses are arranged so as to enable them to keep abreast of modern discoveries. As in previous years, Dr Cox's report presents a comprehensive survey of the whole problem of prevention and treatment of tuberculosis, and the immense amount of information with regard to details of treatment commends it to the consideration of all interested in any side of the campaign against this disease.

Birkenhead General Hospital Centenary

The *Birkenhead Advertiser* published on October 27th a special supplement marking the attainment of the centenary of the Birkenhead General Hospital, and containing an interesting historical sketch of the evolution of that institution since 1828. In that year, when the population of the town was under 3,000, a dispensary was instituted by John Laird, son of the founder of the famous Mersey shipbuilding firm of Cammell Laird and Company, who built or purchased a suitable building and equipped it for the purpose. It was originally intended only for out-patients, but within the first year four beds were added. Seventeen years later a larger building, known as the Birkenhead Hospital and Dispensary and built on a site given by Mr Laird, was opened, with increased accommodation for in-patients. Between then and 1862 the town grew rapidly, the population rising from 24,000 to 57,000, and the need for increased hospital facilities became urgent. When an appeal for public support failed to yield the necessary funds Mr Laird again came forward and offered to provide a suitable building himself. This institution contained 50 beds, with other accommodation on an appropriate scale and was opened in 1864 as the Borough Hospital. Since that time the institution has grown steadily, in spite of financial and other difficulties, and now contains 156 beds. Two years ago the name was changed to the Birkenhead General Hospital. The most pressing need to-day is for funds to cover the cost of the

new out-patients' department, which it is hoped to open free of debt at an early date. Towards the sum of £20,000 required a certain amount has been received, and a special centenary appeal has been made for subscriptions to make up the balance. The *Advertiser's* supplement contains much interesting matter, including photographs and sketches of old and new buildings, reprints of old reports, and reproductions of a dietary list issued in 1870, and of an appeal made in 1862. A statistical summary shows some striking comparisons between conditions in 1864 and those prevailing in 1927, the number of in-patients increased from 351 to 1,707, and out-patients from 4,590 to 15,672, rates rose from £2 12s 6d to £49 12s 3d, the cost of drugs, bandages, and surgical instruments was under £232 in 1864 and over £2,648 last year, when salaries and wages absorbed £5,850, against £286 in the earlier year.

East Suffolk and Ipswich Hospital

Princess Mary opened the new pathological department of the East Suffolk and Ipswich Hospital on October 20th. In connexion with this ceremony a descriptive booklet was published containing a short account of the events which led up to the establishment of the laboratory, particulars of its building and equipment, and a short history of the hospital. At the birth of the Ipswich Hospital in 1836 it was described as "an Asylum for the Halt, the Lame, and the Blind", developments and expansion gradually followed, the most important of which was the opening of the war memorial wing in 1924 by the Duke of Connaught. This wing comprised separate surgical and medical wards and open air balconies, gynaecological and maternity departments, an operating theatre, a large lecture room, and accommodation for uro-genital and special cases. Three-fourths of the existing property and equipment of the hospital has been added during the last twenty years. The new laboratory, which has been erected as a separate building at the north-east corner of the hospital, includes a waiting room for patients as well as the biochemical and pathological departments, leading out of the chemical laboratory is a dark room for photographic work in connexion with pathological specimens. Part of the general laboratory on the first floor is partitioned off by plate glass to form a vaccine preparation room, and in close connexion with it are rooms for section cutting, sterilization, and autoclaves. The whole building is lighted throughout by electricity, the totally enclosed type of shadowless lamp having been installed, the switches and other fittings are constructed with non-metallic substances. The equipment of the laboratory is fully up to date, and it is believed that the building will provide adequately for the pathological work of the hospital and the surrounding district for many years to come.

Ultra-violet Ray Treatment at Massage Establishments

The Public Control Committee of the London County Council is proposing that in all licences to carry on massage or special treatment establishments at which the administration of ultra-violet ray treatment is authorized the following condition shall be inserted: "That ultra-violet ray treatment be administered only in accordance with directions given by a registered medical practitioner with reference to each person to whom such treatment is given, and only by such persons as may be approved in that regard by the Council." It is stated that recently applications have been submitted for consent to give ultra-violet ray treatment at certain massage establishments already subject to general conditions attaching to licences, and it is felt desirable that the regulations should embody a condition designed to secure adequate medical guidance in the use of the new treatment.

Harrogate Infirmary Contributory Scheme

At a half-yearly meeting in connexion with the Harrogate Infirmary contributory scheme held recently, it was announced that as a result of an agreement reached between representatives of the Infirmary and the Knaresborough board of guardians, contributors could now be admitted to the institution infirmary at Stockwell Road, and paid for out of the funds of the contributory scheme.

Mr J R Whiteloy, presenting the report of the executive committee, said that the vast majority of the large business concerns in the town were working the scheme, but many small ones had not yet joined. The most satisfactory method of obtaining subscriptions was by the co-operation of employers and employed. There had been some discussion owing to the fact that it was necessary to obtain a medical certificate as well as a voucher for admittance to the Infirmary. No certificate was required in urgent cases, but a certificate was thought necessary in a general way to prevent trivial cases being brought forward. A proposal for the formation of ward committees was adopted, it was felt that the introduction of such a scheme would popularize the whole movement. The chairman, Mr Herbert Frankling, mentioned that the general committee had decided that maternity treatment should not be a benefit under the contributory scheme. Such treatment in special cases was already provided for both by the municipality and by the county council. If the treatment were placed under the contributory scheme there might be some question whether the municipality would go on paying.

Scotland.

Hospital Services in Scotland

SIR JOHN GILMOUR, Secretary of State for Scotland, on October 25th opened a bazaar at Falkirk in aid of the Falkirk and District New Infirmary Appeal Fund, the object of the bazaar was to raise £5,000 to complete the sum of £100,000 necessary to erect the new buildings. Sir John Gilmour said that as the Minister responsible meantime for the health of Scotland, he observed the work in Falkirk with satisfaction. There were coming more and more to recognize that the great institutions of medical services must direct their attention not so much to curing disease as to taking preventive measures. Fortunately science and teaching were showing the way, and in Falkirk something was being done which would enable science and the devotion of doctors and surgeons, as well as nursing staffs, to put into effect the teaching of science. In the co-operation of voluntary effort it was necessary to link up with all the local authorities around them. One of his efforts in the reforms he was now proposing was to make more and more certain of that co-operation. He was happy to think that in Falkirk recognition both by the workers and by the authorities had led to combination in dealing with the problem of maternity and child welfare. Housing was another aspect of the problem and the clean houses in which people could live with a greater amount of fresh air than in the past were going to be of vital assistance to doctors and sanitary authorities throughout the country. These were examples of the things in which a combination of effort was necessary and essential.

Congested Areas in Edinburgh

Dr William Robertson, medical officer of health for Edinburgh, in an address given under the auspices of the Edinburgh Women Citizens' Association on October 23rd said that it was too late to blame anyone for the apathy that prevailed in the matter of slum clearance schemes. The situation, however, must be faced, and a systematic campaign conducted for rehousing people who required alternative accommodation on account of insanitary conditions. At present in Edinburgh the sanitary inspector had on his books 5,035 individual houses which were considered unfit for human habitation, and in time some of these would be included in slum clearance schemes. There were, however, many isolated properties scattered over the municipal area which could not be embraced by the improvement schemes. It was necessary, therefore, that municipalities should provide houses for persons whose dwellings were insanitary but did not fall within improvement schemes, as well as for those whose houses were situated in slum clearance areas. At present an anomaly existed in the fact that a householder was entitled to a comparatively cheap municipal house if he had been dispossessed as the result of a slum clearance scheme, while

the unfortunate tenant who had been living in an insanitary dwelling had to pay a dearer rent because his condemned house did not happen to be included in such a scheme. This led to much disappointment. The speaker believed that in the course of ten or twelve years they could break the back of the housing needs of the necessitous with an annual contribution of 500 new dwellings, but of these a certain number should be set aside for people who lived in condemned dwellings not included in improvement schemes. Probably fifteen or even twenty years would elapse before slums became rare sights in the city.

The Doctor and the State

A lecture was delivered in Edinburgh by Dr Chalmers Watson on October 24th, under the auspices of the Combe Trust on "The doctor, the individual, and the State." Sir John R. Findlay, who presided, in introducing the lecturer drew attention to the aims of the founder, who, he said, held that man's happiness and prosperity in life depended to a large extent upon his knowledge of the laws of nature. George Combe had written his disposition in 1843, but the principle was as true to-day as when the lectures were founded. The lecturer said that the mean duration of life had increased 50 per cent in the past fifty years and during this period great departments of public health had been evolved dealing with national health insurance, maternity and child welfare, tuberculosis services, laboratory services, and so on. The activities of these bodies had centred largely on questions of general hygiene, and their success had been due mainly to their influence on the external environment of individuals. In the matter of personal hygiene, however, the position had, unfortunately, been otherwise. Except in the matter of excessive use of alcohol, the generation now in the vigour of life committed the same indiscretions as their grandfathers with the result that several common diseases—such as rheumatism, arthritis, high blood pressure, and cancer—showed no diminution in frequency or deadliness. An increasing body of medical opinion was convinced that, whatever the ultimate cause of these conditions might be, the most important cause was the lowered resistance induced by persistent neglect of laws of health. Bacteria played an important part in the causation of disease, but these were for the most part normally present in the digestive tract or other tissues, and were, during health, innocuous. It was essential to recognize that the sudden death from heart disease of a man aged 60, the sudden onset of apoplexy in a man at his desk, and the crippled joints of rheumatoid arthritis were merely terminal incidents in a slow premature degenerative change due, for the most part, to preventable causes. Death was inevitable, but physiological old age and death was one of the rarest occurrences. The life of a man comprised three epochs—an ascent up to 20, a plateau from 21 to 45 or thereby, and a descent. Under modern conditions the period of ascent was disturbed by many incidents or diseases, arising from neglect of nature's laws, but the diseases from which they died were essentially labels attached to the end-products of disease, and the names gave no indication as to the cause. The cure of these conditions lay in prevention. The spread of knowledge would reveal that disease and premature death were the logical outcome of causes which man could himself control, while no miracle could deliver him from the result so long as he persisted in cultivating the causes. The smooth working of the alimentary system was one of the most important factors in man's continued existence, and the ignorance which prevailed on the subject of dietetics was responsible for much preventable illness and many premature deaths. The theory that the role of the doctor was to enable society to go on without suffering was still too much in vogue, and students were taught not how disease might be prevented and cured by a rational system of living, but how its symptoms might be relieved by synthetically prepared drugs. Disease never attacked a healthy organ, and there was too much persistence of ancient superstition and of the belief in "the bottle" which had been referred to as characteristic of many millions of their countrymen. The natural extension of the admirable preventive work carried out recently by public health authorities should involve a satisfactory

linking up of the services of the family practitioner, and would also involve a reform in medical education. The development of a campaign for health would bring the numerous campaigns against disease—cancer, rheumatism, tuberculosis, heart disease, etc.—into a truer and wiser perspective.

Municipal Scheme for Artificial Sunlight.

The Corporation of Edinburgh has decided to take steps to make ultra-violet radiation available for purposes of treatment to the citizens generally. An installation at the Portobello Baths was inspected on October 23rd by members of the town council, when it was explained that this was intended in the main for healthy persons who were run down and in need of a tonic, although special cases, medically certified as suitable for applications of the mercury vapour lamp would be taken. Dr Robertson, medical officer of health, said that the installation of two open arc lamps and a mercury vapour lamp had been made on account of the fact that similar establishments in England had proved a success. The human being might suffer considerably if continuously deprived of sunlight, and, for example, rickets might develop among children which could be cured by a course of artificial sunlight treatment. This new form of medication had got into the hands of people who exploited it as a money-making scheme. Artificial sunlight was not a cure for all diseases by any means, and its scope was limited to the treatment of a few conditions, quackery must be guarded against by the general public, and therefore medical supervision would be strictly exercised in the use of these lamps, the mercury vapour lamp would be used only upon the advice of a doctor. The new service will be reserved three days a week for women and three days for men, at a moderate charge.

Ireland.

School Medical Services in the Free State

GENERAL R. MULCAHY, Minister for Local Government and Public Health in the Free State, in a recent address on school medical services, said that the organizing of these services must be regarded as fitting the keystone in their modern health system. It provided public health authorities with a vantage point of enormous value, not only for the direct prevention and treatment of disease, but for the education of the individual. In addition, it would provide very valuable localized statistical material, which would help very considerably in dealing with problems of environment. The modern public health movement, which began in the early part of the nineteenth century, reached its third phase in recent legislation dealing with personal hygiene. Its first stage was principally characterized by the development of waterworks and sewage disposal systems, and its second by more effective control over contagious diseases. The importance of personal hygiene was, however, recognized from the very start, the delay in its case was due to the fact that in respect of this phase of public health reform, more than of any other, popular education for the acceptance of its principles was required. School medical inspection was introduced in Great Britain in 1907, but it was not until 1919 that the Public Health Medical Treatment of Children (Ireland) Act devolved this duty on county and county borough councils. Describing the system now prevailing in Dublin, he stated that the child in the primary schools would be subjected to inspection at three ordinary periods of the school life—on entrance, at the age of 8, and on leaving. In addition, any child who came under notice for defects might be specially examined. The system, General Mulcahy said, had been instituted only this year, and up to the present, out of a total of 173 schools, 56 had been examined. There was splendid co-operation in spite of some great difficulties, on the part of the school authorities. The facts brought to light by the examination had been in many ways a source of satisfaction. Among 10,752 children examined in Dublin there were only 42 cases of non-pulmonary tuberculosis, 20 cases of definite pulmonary tuberculosis and 18 cases of suspected pulmonary tuberculosis, this being less than 0.8 per cent of the children

inspected Rickets appeared to be almost non-existent where, because of poverty and other causes, many cases might have been expected. So also was personal uncleanliness. The principal defects were shown to be dental caries (5,336 cases, or 46 per cent of the children inspected), tonsils, adenoids, etc (2,248 cases, or 21 per cent), eye defects (2,609 cases, or 24 per cent), malnutrition (594 cases, or 5.5 per cent). Where treatment was necessary arrangements were made for it either at the hospitals or at a special clinic. It was estimated that the total cost for next year in Dublin would be about £5,000, half of which would be contributed from central funds. All close students of the economics of public health finance were satisfied that no other activity on the preventive side gave a more direct return than the early diagnosis and treatment of children's ailments. The cost per child was trivial, but it purchased an increase of health, happiness, and efficiency for the individual, and, therefore, in a wider degree, for the community at large, and saved many a permanent incapacity. The staff of the school medical service for Dublin consisted of two school medical officers, two school nurses, and clerical assistants. In Cork City, where a scheme had been in operation for four years, the arrangements were fully developed. During 1927 the following received treatment: (1) at Eye, Ear, and Throat Hospital and by private practitioners—(a) operative treatment, 187, (b) refraction, 499, (c) glasses prescribed, 483, (2) at school clinic—minor ailments, 412, (3) at Dental Hospital and by own dentist, 1,277. In Limerick county borough arrangements for the appointment of an assistant medical officer of health, to whom will be assigned the duty of school medical inspection, and of a whole-time nurse have been sanctioned. Waterford, alone of the county boroughs, had not moved in the matter. In Clonmel a scheme worked by a part-time staff was giving satisfaction. In counties where county medical officers of health had been appointed schemes were being formulated and officers appointed. In Offaly two school medical officers, with the assistance of a temporary staff of nurses, had begun the preliminary survey of the children, permanent nurses were to be appointed. In addition to the county medical officer of health, an assistant had been appointed in Kildare at a salary of £600 for school inspection. The Cork staff consisted of one chief school medical officer and the county medical officer of health, three school medical officers were recommended for appointment, and six school nurses were sanctioned, but the appointments had not yet been made. In Louth two whole-time nurses would be appointed without delay, and meanwhile the county officer of health would start the preliminary survey with the aid of a temporary nurse who was undergoing a course of training in Dublin. The Minister, in conclusion, said that they had started fairly systematically on the work, and already, in the case of thousands of children in the country, defects had been remedied at very early stages. They were quite satisfied that, although the work had only begun, they had ensured much greater happiness, health, and efficiency to a fairly large number of the population.

Correspondence.

TROPICAL AUSTRALIA

SIR,—Dr Andrew Balfour, in the *British Medical Journal* for May 19th (p. 875), put to me a definite question. May I point out that I live 1,500 miles from the cane fields, and also that the precise answer to his question cannot be given till the census of 1931. In the meantime, however, Dr Cilento, director of the Division of Tropical Hygiene in the Commonwealth Medical Service, has furnished me with information, which is as follows:

The Italians in Queensland come mostly from north Italy. In 1921 there were in the whole of Queensland only 1,838 Italians, including women and children. In the tropical coastal belt the population was 103,000, of which Italians were less than 1 per cent—that is, between 850 and 900. It was at this juncture that Dr Cilento wrote "The white man in the tropics—that is, before the Italian immigration. With American restriction the tide set in

to Australia, and whilst in all Australia there were in 1921 4,903 Italians, by 1927 there were 23,120 additional, of these approximately 7,000 went to tropical Queensland, giving a total population in that part of Australia of about 8,500 in a population of 120,000—that is, about 7 per cent."

Sugar growing in Queensland dates from 1905, and up to 1921 was conducted by Anglo-Saxon labour almost exclusively. In certain limited areas on the cane fields the Italians constitute a large proportion, one-half, and in one instance more than one-half of the population, but the condition is only of five years' duration. On sugar production, as a whole, there are 30,250 men employed, and of these the Italians number 2,700, or about 9 per cent. The unions assert that the Italians take two hours longer to do a day's work, and consequently upset awards of the court. On the other hand, they are easier people to handle from the employers' point of view, and consequently this statement and grievance must be left for proof and further investigation. As regards Dr Balfour's previous question, there are no fourth generation people in tropical Queensland, because the country is not old enough.

Dr Cilento adds that, as to areas where Queenslanders of the second and third (resident) and second (born) generation do the manual labour, any part of northern Queensland may be cited. The condition is very general.

In conclusion, I only wish it were possible for friends like Dr Balfour to visit tropical Queensland and examine the problem personally, we should warmly welcome them. If they then moved to the mandated territories nearby they would see within a few days what damage an infected native population can do. Australia is most fortunate that she does not harbour so destructive a factor.

The medical services in the mandated islands are doing their best and making an honest attempt to control disease amongst the natives, but only those like Dr Balfour, or perhaps the writer, who have tried to do such work, appreciate the magnitude and complexity of so colossal a medical problem—I am, etc.,

Melbourne Sept. 7th.

JAMES W. BARRETT

FAMILIAL GLIOMA RETINAE

SIR,—The glioma family described by Mr Letchworth in your issue of October 13th (p. 656) brings to my mind a not dissimilar family history.

A baby boy (aged 9 months, I believe) was operated upon by the late Dr Argyll Robertson for glioma of the left retina. He recovered and grew up, he married, and had four children. Of these the first was described to me as stillborn, I do not know the cause of death of the foetus. The second child (first living birth) and the following, a girl and a boy, both died of double glioma at the age of approximately 4 years. The father absolutely refused to allow operation, although without operation he would never himself have grown up—but perhaps from the racial, if not from the individual, point of view he may have been wiser than we were. The fourth child, when last I saw her as a little girl of 3, was apparently quite healthy. She was a posthumous child, for in the meantime the father who had been serving in France in the army, was sent home ill and died of multiple intracranial new growths.

It seems more than strange that an infant rescued from death by glioma should have grown up to procreate four children, of whom two at least died of that disease, and that he himself should then have died of it at the age of 27. With the commentary in Mr Letchworth's last paragraph one must sadly agree—I am, etc.,

WILLIAM GEORGE SIM, M.D., F.R.C.S. Ed.

Edinburgh Oct. 22nd

SANOCRY SIN, SUNLIGHT, AND THE SKIN

SIR,—All workers in tuberculosis will have read with great interest the authoritative article by Dr L. S. T. Burrell on the value of the heavy metals in pulmonary tuberculosis in your issue of October 27th (p. 737).

There is one very important complication of sanocrysin to which I have not found reference in the literature, and that is the effect of sunlight on the skin. One of my patients, who had received sanocrysin returned from Switzerland with a blue-coloured pigmentation of the face

and neck, only those parts being affected which had been exposed to the sun. Thus the forehead shaded by the hair was quite white. The colour was noticeable to the patient and her friends, and made her appear as if blue from cold even on a hot day. I have subsequently heard of two similar cases, and in one, I understand, a section of a portion of the skin showed a deposit of gold there.

This noteworthy complication serves as a warning that no patient who has had a course of sanocrysin treatment should expose himself to bright sunlight. Whether injections of sodium thiosulphate would be a safe therapeutic measure and likely to afford relief is a point on which information would be welcomed—I am, etc.,

London, 11 Oct 27th

G E BEAUMONT

QUININE BLINDNESS AFTER INJECTION OF VARICOSE VEINS

SIR,—In Mr G H Colt's article on the modern treatment of varicose veins, published on September 22nd, the following words appear at page 526

'We must also remember that quinine sometimes produces blindness. The risk is said to be about 1 in 1,600

"If it were so it was a grievous fault," and so great a risk should be an absolute contraindication to the use of quinine in view of the fact that all "efforts to combat the blindness have had but one uniform result—complete and absolute failure" (Smith, *Trans Ophthal Soc*, 1919, xxxix, p 316), but is it so?

On looking up Mr Colt's reference (loc cit, p 315) I find that the following is stated

Dosage—Blindness occurred with doses varying from 35 gr to 90 gr administered during the preceding twelve hours. In the case where only 35 gr proved toxic 20 gr were administered intramuscularly. The average toxic dose for the others was 65 gr. Four cases had oral quinine alone, one intramuscular alone, and the remainder had both oral and intramuscular. No relation could thus be established between the degree of toxicity and the method of exhibition of the drug. (My italics)

The minimum dose was 35 grains

In injecting varicose veins with Douthwaite's solution of quinine-urethane, 2 c cm contain 4 grains. If we are very reckless and give 3 c cm the dose is 6 grains, or about one-sixth of the minimum toxic dose in Smith's series. Are we to understand that the intravenous administration of 6 grains of quinine is in any way comparable with the 35 grains in Smith's series—especially in view of the fact that the dose is only repeated once or twice a week? Unless this is proved to be so, the risk of quinine blindness—like that of pulmonary embolism following injection treatment—should be relegated to the limbo of exploded bugbears—I am, etc.,

Hove Oct 23rd.

ST GEORGE B DELISLE CRAV

SAFETY IN ANAESTHESIA

SIR,—Among the recent letters written on the subject of anaesthetics for tonsillectomy I have not noticed any reference to the use of a chloroform and ether mixture given in a Clover's inhaler without a bag—that is, an open method. For many years past I have largely used this method of anaesthesia, and have found it to give consistently good results.

To induce anaesthesia six fluid drachms of chloroform and twelve fluid drachms of ether are freshly mixed in a conical measuring glass, and are then poured into the Clover's inhaler. The latter is next warmed by holding it under a hot-water tap for a few seconds. No bag is used, so there is no re-breathing. The mask being applied to the patient's face, the cylinder is very slowly rotated until, in the case of adults, full strength of vapour is being inhaled. As soon as complete anaesthesia is obtained the cylinder is slowly rotated back to the extent that is found by experience to be necessary for the maintenance of the anaesthesia.

It is important that the mask should never be removed from the face for a single moment during the operation. More anaesthetic can be added from time to time without the need for this. The anaesthesia obtained is remarkably quiet and there is a complete absence of stertor and of salivation. Morphine or atropine, or a combination of both, can be given or not beforehand as desired.

The chief danger in the administration of chloroform or of ether and chloroform mixtures lies in the risk of an overdose from the heavy chloroform vapour which is given off from a more or less saturated mask of lint or gauze. This risk is entirely obviated in the method that I have described, as in this a uniform proportion of anaesthetic is inhaled with each breath. In the case of long operations it is as well to change to "open ether" at the end of about an hour.

I do not recommend the method for men of a burly type, though anaesthesia can be obtained with them if occasional re-breathing into a bag is practised at the beginning of the induction. For obstetric work—especially if single-handed—I find the method invaluable, as after anaesthetizing the patient one has only to rotate the cylinder to a perfectly safe position and then give it to an assistant to hold in place—I am, etc.,

Guildford Oct 22nd

H F PARKER

ANAESTHESIA FOR TONSILLECTOMY AND REMOVAL OF ADENOIDS

SIR,—Your correspondent Dr W R Somerset (October 20th, p 726) invites comments on his letter. The question whether the children who have tonsils and adenoids removed are cured concerns the surgeon rather than the anaesthetist. It is certainly an important point, and no doubt in some cases there is sinus infection.

To explore these cases thoroughly it is not necessary to give ether as Dr Somerset suggests, it can be easily accomplished with nitrous oxide and oxygen—a more transient anaesthetic agent than even ethyl chloride. This last week I saw Dr de Caux give nitrous oxide and oxygen with a McKesson machine through an intratracheal catheter for four operations for the removal of enlarged tonsils. The operations were performed by Mr Abel at the Woolwich War Memorial Hospital. He dissected out the tonsils and took plenty of time to see that the cavities left by the removal of the tonsils were quite free from oozing before the patients left the operating table. The surgeon said that he was quite satisfied with the anaesthetic.

My own method for the nasal, antral, and sinus operations is to anaesthetize the patient with nitrous oxide or ethylene and to introduce quickly a Kuhn's tube into the larynx, the pharynx is then packed off with gauze, and the gas supply is continued through the tube by means of a fitting which was made for me by Messrs Pegler Brothers, brass founders, Doncaster.

There is no limit to the length of time the anaesthetic may be continued in this way—the longest I have experienced up to the present is about one hour, and the anaesthesia has been satisfactory so far. The patients have made a very speedy recovery.

If I may make an observation on anaesthetics for general work apart from the tonsil and adenoid operation I would like to say that in my opinion it is unkind—to say the least of it—to give ether or more dangerous anaesthetics to patients when nitrous oxide and oxygen will suffice. I know that some surgeons say they cannot operate with it but then there are some surgeons who put into an abdominal wound a retractor about the size of a fire shovel and say "pull on this sister!" Believe me, it takes some anaesthetic to stand it—I am, etc.,

Doncaster Oct 22nd.

E J CHAMBERS

SIR,—I have seen the above letter written by Dr E J Chambers on the question of nitrous oxide anaesthesia through a Kuhn's tube with a McKesson machine. He has given a number of anaesthetics by this method for me, and I am satisfied that any operation on the nose and pharynx can be satisfactorily performed with it.

As to laryngeal or oesophageal work with gas and oxygen, I have not had sufficient experience with it yet, except that I have dealt with a case of an impacted denture in the oesophagus with an oesophagoscope, using gas and oxygen anaesthesia. The anaesthetic was satisfactory, and did not hinder my work.

All the patients made better and much quicker recoveries from this anaesthetic than with ether, but in my

opinion the success of the administration of the nitrous oxide gas and oxygen depends entirely on the McKesson machine and efficient handling—I am, etc.,

Doncaster Oct 22nd

HUGH M PETTY

SINUS DISEASE IN CHILDREN

SIR,—Whilst somewhat irrelevant to the subject, Dr Somerset's tilt on October 20th (p 726) at the laryngologist opens up a question which merits the close attention of all concerned. Every experienced laryngologist will admit that the operation, as such, has its limitations, and that there exists a very definite percentage of children who derive little or no benefit. If he is inclined to the opinion that Dr Somerset overestimates this percentage, it may be that the very nature of his work as a consultant prevents him from following up what must constitute a big percentage of his cases. I think, however, having tried the procedure, and with a long experience of the work, that the routine exploration of the nasal sinuses, while ideal in theory, will be found to be an impracticable proposition, at least in the routine work in hospital.

The important point is the recognition, however tardily, of the fact that sinus disease is a concomitant affection in a small but definite percentage of children suffering from respiratory ill health, and that a failure to obtain relief by the removal of the more obvious cause necessitates the subsequent exploration and eventual drainage of the affected nasal sinus or sinuses.

A mutual recognition of the probabilities and of the possibilities of each case should obviate the difficulties to which Dr Somerset has rightly drawn attention, or at least help to solve them—I am, etc.,

October 29th. J B HOROAN, M.B., Ch.B., D.L.O.,
Honorary Laryngologist North Infirmary, Cork.

TRAUMATIC SEPARATION OF AN INTESTINAL LOOP

SIR,—I have noted the memorandum under this heading on page 611 of the *British Medical Journal* for October 6th. It may interest the writers of the memorandum and others to refer to the *Journal* for Mar 29th, 1909, where on page 1290 I have recorded the case of a man, aged 40, who received a blow on the abdomen from a piece of iron. At operation a piece of small intestine four inches long, with mesentery, was found loose in the abdominal cavity—I am, etc.,

Cardiff Oct 24th

A W SHEEN

FUNCTION AND POSTURE

SIR,—With reference to Dr Peter Macdonald's letter in your issue of October 20th (p 725), I should like to add my testimony to the value of the work being done by Mr F Matthias Alexander. I have undergone some preliminary education at his hands, and as a result I am convinced that the importance of the last paragraph of Dr Macdonald's letter cannot be over-emphasized.

If there is any possibility of Mr Alexander so crystallizing his technique that it can be transmitted and taught practically in medical schools I believe the next generation would see the biggest advance, not only in preventive medicine, but also in constructive civilization, that has ever been noted in so short a time.

The difficulty of bringing this work practically before the profession lies largely in the obstacle that Dr Macdonald mentions—that of using words to convey the meaning of a sensory appreciation, but we have all met this problem, and solved it to the point of practical use, in trying to learn something of percussion, auscultation, and other matters of our daily work, we have arrived at this working solution by a combination of words, demonstration, and experience.

I believe that a team of competent anatomists, physiologists and psychologists, with Mr Alexander, could arrive at a formulation of technique that would at least provide a starting-point from which the profession could adopt it, and develop it in use, till the idea of treating the human organism as a whole would become an actual fact and not merely a pious hope—I am, etc.,

Manchester Oct. 23rd.

R G MCGOWAN

SIR,—If I may be permitted to do so, I would wish to endorse, in the strongest manner possible, the remarks of my friend Dr Peter Macdonald in your issue of October 20th. I have known Mr Matthias Alexander for some years, and have not only closely watched his methods, but have put myself and others into his hands with incalculable benefit. The improvement in every case which he has undertaken with my personal knowledge has been very marked, and I consider that, in his teachings and technique, our profession, if it will but shake itself free from the trammels of tradition, has an aid to treatment of the utmost value.

There is no need to speak further upon Mr Alexander's work, as Dr Macdonald has said all that is necessary, but I would urge, with him, the grave necessity of preventing such an important teaching from being lost to us. Steps should be taken without delay for the training of selected pupils under Mr Alexander's personal supervision in order that his great work may be carried on, especially among children—I am, etc.,

London W 1 Oct 23rd.

MACLEOD YEARSLIE

INTESTINAL AMOEBIASIS IN BRITAIN

SIR,—The cases quoted by Dr Venables in the *British Medical Journal* of October 27th (p 775) of miligenous amoebic dysentery in this country are of considerable interest.

As regards diagnosis it is a common occurrence for the stools to be negative to free forms of *E. histolytica* in cases of relapse in amoebic dysentery, though cyst forms may sometimes be found.

It has been for some years the practice in this hospital to use the sigmoidoscope on all doubtful cases, and the lesions which may be found are well shown in a series of excellent water-colour paintings by Dr P H Manson-Bahr, executed at sigmoidoscopies in the theatre of this hospital, and now exhibited in the museum of the London School of Hygiene and Tropical Medicine.

It is the experience here that swabbing a lesion is insufficient to obtain *E. histolytica* in many cases, but the taking of a scrapings with a long-handled spoon via the sigmoidoscope is usually successful. Sigmoidoscopy, once before and once after treatment, should be enough, and beyond subjecting the patient to a great deal of unnecessary discomfort little is to be gained from repeated examinations.

Treatment with emetine injections is not, in my experience, nearly as successful as the "combined treatment" of emetine bismuth iodide by mouth and yateren lavage per rectum. The combined treatment is noteworthy for the absence of relapses, whereas it is not uncommon for cases which have had repeated injections with emetine to show improvement for a while and then relapse. A cure with 9 grains of emetine would be exceptional and improbable.

The "combined treatment" used is as follows. Emetine bismuth iodide 1 gram, increasing on the second night to 2 grains, on the third night to 3 grains, and continued in doses of 3 grains for ten nights. The drug is given at 10 p.m. in capsules, the patient being in bed and lying flat without pillows, to prevent vomiting.

Daily, each morning, lavage with a 2½ per cent solution of yateren is given, and the wash-out is retained for as long as possible. Most patients can retain this for six to eight hours, and many for eighteen hours or longer. If well tolerated the solution is given in 5 per cent strength on the fifth day. The lavage is employed for ten days in all. The total duration of treatment is twelve days, after which the patient is discharged, with instructions to take two yateren pills daily for a month. I understand that in this hospital during the last two and a half years there have been no relapses even in the most resistant and chronic cases of intestinal amoebiasis.

For the general practitioner it is a matter of comparative simplicity to have a stool sent for examination; a minute quantity only is needed. Sigmoidoscopy cannot be classed as a simple procedure, few medical men possess a sigmoidoscope in the first place, and I venture to suggest still fewer would know what to expect to see with it, or even how to use it properly, unless they had adequate instruction.

Stool examination is so frequently successful, especially when repeated daily three or four times, and in particular in first attacks, that every encouragement should be given to this mode of diagnosis, provided the examination is in the hands of an expert pathologist and protozoologist. The sigmoidoscope must remain for a while an instrument for a specialist—I am, etc.,

TESTING FOR COLOUR-BLINDNESS

SIR,—I have been greatly annoyed to find my name on caricatures of my lantern. One lantern had actually a yellow glass labelled purple. All authorized lanterns are accompanied by a certificate signed by me stating that they are correct.

I understand that a number of unauthorized "Edridge-Green" lanterns are being used in India, and I hope Indian newspapers will take note of this disclaimer—I am, etc.,

THE DEFINITION OF DRUNKENNESS

SIR,—The interesting letter in the *Journal* of October 20th by Dr Sidney Matthews raises a question of serious importance to the general public. No doubt the decision by the chairman of the quarter sessions was good law, but it certainly indicates the need for the law to be changed. I believe that many motor accidents are due to the effects of alcohol without the motorist himself or anyone else having the least idea that this is the case.

The general public do not realize the fact that even a small amount of alcohol has a definite effect in lessening the ability of an individual to control his actions. The carefully conducted experiments by Professor Kraepelin have proved beyond doubt that quite small doses of alcohol have these effects: (1) the rapidity of cerebral action is delayed, (2) the power of judgement is lessened, (3) the individual develops an illusion that both the rapidity of his actions and his power of judgement are enhanced. So, owing to the illusive influence of alcohol, he acquires a condition of over-confidence which may lead him to take risks which at another time he would avoid, and this just at the time when his powers, both of judgement and of rapid co-ordinated action, are diminished. A delay of the fraction of a second may make all the difference between safety and disaster, for let it be remembered that a motor car going at quite an ordinary speed may travel 15 yards in a second.

The public require instruction in this matter. Then perhaps a change might be made in the law of such a nature that a medical certificate, like the very appropriate one given by Dr Sidney Matthews, would have the effect that it deserves—I am, etc.,

ULTRA-VIOLET RAY THERAPY

SIR,—I have read with interest the papers by Dr W E Dixon and Dr C B Heald in your issue of October 13th, and I consider that they prove in a very able manner that it is highly dangerous for artificial sunlight to be given by non-medical persons, and the proposed register should be of great value.

The subject is largely a new one, and I quite agree that most absurd statements have been made by some persons as to ultra violet rays being a cure for all manner of diseases yet, as with other treatments in the past we are finding certain conditions in which we are obtaining very successful results and in several of these cases Dr Dixon's comments were hardly encouraging.

He states that physicians are generally agreed that radiation by ultra-violet light is contraindicated in nervous and neurotic people. I had such a case sent to me for this treatment by a distinguished nerve specialist. The patient, a young adult, had received very extensive treatment elsewhere, and was still in a highly neurotic condition. Her response to small doses from the carbon arc lamp was excellent in every respect, I agree that excessive doses would be

likely to aggravate the condition, but in general I have found the effects beneficial if the treatment is proficiently carried out. The effect is probably obtained by action of the rays on the phosphorus and calcium metabolism. The Commissioners of the Board of Control, in their report for 1925, comment favourably on the results obtained by treating neurasthenic patients with ultra-violet rays.

Dr Dixon states that the carbon arc light is not only the best substitute for sunshine on technical grounds, but gives the best therapeutic results. I quite agree with this so far as general treatment is concerned, but he makes no reference to local treatments, unless he is thinking of those when he suggests that many of the metabolic effects are obtained just as well with, "say, a mustard plaster." Certain local skin infections respond in an extremely favourable manner to first or second stage erythema doses given with a mercury vapour lamp. I will illustrate this by recalling a case of herpes zoster in which severe pain had persisted for seven weeks without being alleviated by ordinary methods. The patient's pain and discomfort were considerably relieved even after the first exposure, and at the end of six treatments the symptoms had almost completely disappeared.

I quite realize that Dr Dixon has brought forward his instances in order to point out the great dangers that may arise from treatment given by unqualified persons, and I agree very heartily with his observations on this subject. I feel, however, that his paper will be read by a large number of practitioners who have had little opportunity themselves of seeing the effects of treatment, and that certain observations which I have attempted to draw attention to might cause an unfavourable impression which I think Dr Dixon had no intention of conveying—I am, etc.,

C H C DALTON, M D, D M R E Camb,
Medical Officer in charge X rays and Electro-Therapy
Department East Suffolk and Ipswich Hospital
Ipswich Oct. 25th

SIR,—The tirade by Dr Whatoly Davidson (October 13th, p 676) seems to me rather uncalled for. What has he against the "Sun-ray" Company, anyway? First, apparently, that a company should dare to make money out of physiotherapy. Does he not make money out of medicine? Do we not all try to earn a living? Then he states that "Wherever there is a supply of electricity there is now a doctor who is conversant with the recent literature on this subject and prepared to give ultra-violet ray treatment." Prepared, maybe, but is he capable? Has he the necessary apparatus and appliances, which are numerous and costly, or the time and experience? A general practitioner would not dream of trespassing on—for example—the eye specialist's preserves, even if he had read the latest literature on the subject, so why should he on those of the actinotherapist, which are just as specialized?

Dr Davidson speaks of the company "telling the world," and the whole-time doctor being denied a free hand and tempted to treat anyone who likes to come along. He cannot have read very closely the circular letter, which states that "the board would prefer to receive patients who have been referred to them by their medical attendants, who will, if they desire them, receive reports of treatments." Why should he assume that the companies' activities will not be kept "within the recognized limits of medical etiquette and ethics"?

Surely a clinic run professionally with a financial backing can give far better and more varied treatments to the largest number of patients than a general practitioner with limited capital and time, and surely a big company working in conjunction with members of the profession is the best enemy of quacks—I am, etc.,

Bristol Oct 15th

ARTHUR T SPOON

VITAMIN A AND VITAMIN D

SIR—Green and Mellanby, in their paper in your issue of October 20th (p 691), conclude that while vitamin A has marked effect in increasing the resistance of animals to infection, vitamin D has no such effect. This is so completely at variance with the conclusions of Pfaffenstiel (*Lancet*, October 20th, 1928) that some explanation seems

necessary. I need only quote the following passages from Pfaffenstiël's paper:

The effects of deficiency of vitamin D on the full-grown animal organism have been investigated by W. Eichholtz and H. Kreitzmar. Their results showed an obvious lowering of resistance to infectious diseases in rats and mice which had received a diet free from vitamin D.

While the vitamins A, D, B and C contained in foodstuffs exercised by themselves no definite influence, an increase in the bactericidal capacity of the serum was successfully obtained, in young healthy rabbits, by the daily administration of very small doses of vitamin D.

It would thus seem that further work is necessary to clear up this complete discrepancy, and it is to be hoped that this will be forthcoming, since it would be unfortunate if the effects of vitamin D on the human organism came to be prematurely discounted at a time when supplies are so readily available to the profession.—I am, etc.,

H. JERROTT, M.Sc.

INTERDIGITAL RINGWORM

SIR,—Interdigital ringworm of the feet, which was mentioned in Dr. J. M. H. MacLeod's paper published on April 21st (p. 656), has been a very common condition in Santa Cruz. This island has a tropical climate, with a very high rainfall all the year round, and the disease occurs mainly in white men who are timber-getting and have to do a great deal of work in deep mud or wading in salt water. The first signs are a pitting and softening of the skin of the sole, followed by redness and vesication between the toes, with cracking and sometimes extension on to the dorsum. There is intense irritation, aggravated by heat and damp. I could find no reference to the cause of this condition, but I detected a ringworm fungus, apparently the common *Tinea imbricata*. I tried various parasitocides, but most proved to be too irritating, causing pain and cracking. Eventually I found a 5 per cent ointment of copper oleate most satisfactory. Scales and thick softened skin are best detached by scrubbing with fairly strong lye. In the most obstinate cases a little chrysophanic acid may be used, but this is seldom necessary, and is irritating. The feet must be kept dry, and I strongly disagree with Dr. MacLeod's recommendation to soak them, or wade in salt water. This aggravates the disease and prevents cure.—I am, etc.,

Santa Cruz Group, British Solomon Islands, August 22nd

B.S. Adelaide

SECURITY OF TENURE IN PUBLIC POSTS

SIR,—I have read with interest the letter by "A.M.O." on this subject in your issue of October 20th (p. 728). As an assistant medical officer of one of the smaller county mental hospitals for some years I should like to offer a few observations. Dr. W. M. Fraser, in a letter in the *Journal* of October 13th (p. 677), dealt with the security of tenure in public posts and, unless definite evidence to the contrary be forthcoming, I think one may agree that "in practice the danger of dismissal is extremely small." His remarks apply more directly to public health appointments but, so far as I am aware, they apply also to mental hospital posts. It is the remainder of "A.M.O.'s" letter, however, which induces me to reply.

During my service here I have served under two superintendents, and no attempt has ever been made "to prevent as far as possible" any contact with the committee, and both have repeatedly made inquiries with regard to food and general management of the A.M.O.'s quarters and any reasonable suggestion has always been considered and adopted if at all possible. I admit that the junior A.M.O. may not marry, but to say that, in the majority of cases, "if he decides to remain in the service, he must take what amounts to a vow of celibacy" is surely a gross exaggeration. Were all our medical superintendents deputy superintendents, and senior medical officers never junior medical officers? And is it the case that the junior medical officer's chance of promotion, without influence, is almost nil?

With regard to hours of duty, does "A.M.O." want a "clock" arrangement of some kind? I have never had

difficulty in obtaining a morning off if I wanted it, or any other reasonable time. My superintendent was granted study leave some years ago. I obtained it last year, and my colleague has been granted it this year. Yet "A.M.O." says arrangements for post-graduate study are "never made."

Again, almost from my earliest days here efforts were made by the superintendent to instruct me in administrative routine. Thus, by the way, is learned not only in the superintendent's office, but also in the clerk's office, stores, and the other departments of the hospital. In my experience the various officers have always supplied any information asked for, and have also taken considerable trouble to explain the routine work of their departments. The work is not mostly drudgery of a very uninteresting nature. In a small institution, where one has charge of one side, it is varied and interesting. Of course, to a large extent, it is what one makes it.

To compare the position of a junior medical officer with that of a general practitioner is not a fair comparison. Compare it with that of an assistant to a general practitioner, and the advantages of the latter position, so far as I am aware, are doubtful. I have never heard of such an assistant with whom I would care to change places.

Perhaps I am one of the few instances of an A.M.O. working under an "enlightened administration." In any case, the above represents my own experiences, and it applies equally to the time when I was junior A.M.O.—I am, etc.,

Wells, Somerset Oct. 20th

ARTHUR DARLINGTON

SIR,—Your correspondent "A.M.O." in the *Journal* of October 20th (p. 728), has stated the case of the assistant medical officer at an asylum in a manner which deserves attention. May I suggest that the points he ventilates apply equally to an assistant medical officer at a county sanatorium?

In most cases the appointment of an assistant medical officer at a sanatorium is limited to a period of one year, although this period may be extended by reappointment. This is unsatisfactory in so far as it seems to be an attempt to evade the minimum scale of salaries for assistant medical officers in the public health service, as laid down by the British Medical Association. The advertisement for these posts often incorporates the phrase, "no previous professional experience necessary"; this, again, seems to be a deliberate attempt to minimize the value of the services required.

The salary offered for an appointment of this nature is, at the most, £250 with board and lodging, and there is no prospect of any increase. The vow of celibacy as described by "A.M.O." is apparently expected by the authorities, and of necessity taken by the medical officer. Furthermore, the title—assistant resident medical officer—is in some cases almost a misrepresentation of the actual status of the officer holding the appointment, as, although there is ostensibly a staff of three medical officers at some institutions—namely, a medical superintendent, a resident medical officer, and an assistant resident medical officer—the two former may also hold the appointment of county tuberculosis officer and assistant county tuberculosis officer respectively. In this capacity their work will necessitate their absence from the institution for the greater part of each day, so that the onus of all the routine work falls to the lot of the assistant resident medical officer. Such routine work calls for adequate off-duty time, and this should be accepted as a right and not as a favour to be granted by the medical superintendent.

I have pointed out in a previous letter (October 20th, p. 727) the necessity for taking certain precautions before accepting an appointment at a sanatorium. May I now add that it is time the authorities concerned realized that the remuneration and amenities offered are inadequate in view of the risk (and it is a very real one) that is taken? I therefore endorse the recommendation of "A.M.O." that the British Medical Association, which has done so much in the past for those holding public posts, should take up the case of the assistant medical officer.—I am, etc.,

Devon Oct. 22nd.

ALAN J. McMILLAN

Obituary.

SIR CHARLES TOMES, LL D, FRS, FRCS,
Consulting Dental Surgeon Royal Dental Hospital Trustee and
formerly Treasurer of the General Medical Council

WE have to announce with much regret the death, in his eighty-third year, of Sir Charles Tames, which took place on October 23rd at his home, Mannington Hall, Aylsham, Norfolk. The present position of odontology among the medical sciences is largely due to the work and character of two men, John and Charles Tames.

Charles Sissmore Tames, the eldest son of Sir John Tames, FRS, FRCS, was born on June 6th, 1846. Of his father it has been said by Sir D'Arcy Power, in the *Dictionary of National Biography*, that he "began to practise dentistry when it was a trade, and he left it a well equipped profession. The change was in great part due to his personal exertions but he did even more than this, for he showed that a dentist was capable of the highest kind of scientific work—that of original observation." It was through the efforts of John Tames that the Royal College of Surgeons of England instituted a licence in dental surgery in 1858. He was one of the chief founders of the Odontological Society, and of the Royal Dental Hospital, where he was the first to give systematic clinical demonstrations. He was also largely instrumental in obtaining the Dentists Act of 1878. In the last year of his life the John Tames Prize was founded by members of the dental profession to commemorate his services in promoting the study of dental surgery and improving the status of its practitioners. It was most appropriate that the first award, by the Council of the Royal College of Surgeons in 1894, should have been made to his son Charles, who, as recorded below, so worthily followed the same path.

From Radley College Charles Tames went to Christ Church, Oxford, where he distinguished himself as an oarsman, and in 1866 was placed by himself in the first class in the School of Natural Science. He then entered as a medical student at the Middlesex Hospital, where his father had also studied and was then on the staff as surgeon dentist. He obtained the diplomas of MRCS Eng and LDS in 1869, and graduated MA Oxon in 1872. In 1878, largely in recognition of his original studies on the structure and development of the teeth, he was elected FRS at the early age of 32, and twenty years later his pioneer work in dental research was recognized by election to the Fellowship of the Royal College of Surgeons of England. In 1909 the University of Birmingham conferred upon him the honorary degree of LL D, and in 1919 he received the honour of knighthood.

In the earlier part of his professional life Charles Tames practised in his father's house in Cavendish Square, and served as lecturer and assistant dental surgeon to the Royal Dental Hospital. From 1881 to 1895 he was examiner in dental surgery for the LDS of the Royal College of Surgeons. From 1888 to 1920 he was a Crown nominee on the General Medical Council, and for the last sixteen of those years held office as treasurer. In 1910 he was appointed a trustee of the English Branch Council, and nine years later trustee of the General Council, these

offices he held until his death. For a short time, about the year 1895, he had acted as inspector of dental examinations on behalf of the Council, and he served later as chairman of its Dental Education and Examination Committee. He was one of the members of the Commission appointed by the Lord President of Council ten years ago to inquire into the extent and gravity of the evils of dental practice by persons not qualified under the Dentists Act of 1878, and when the Dental Board of the United Kingdom was constituted in 1921, under the Dentists Act of that year, he was appointed a trustee of the Dental Fund.

Apart from his series of important papers on the structure and development of the teeth, and in particular on dentine and the enamel organ, published between 1875 and 1890 in the *Philosophical Transactions* and the *Quarterly Journal of the Microscopical Society*, Charles Tames edited the last four editions of Tames's *Dental Surgery*, and was the author of a *Manual of Dental*

Anatomy, Human and Comparative, which reached its sixth edition in 1904. For many years he was an occasional contributor of unsigned articles on various subjects to the *British Medical Journal*, and often gave valuable help to the Editor on matters relating to dentistry and the proceedings of the General Medical Council, thus the friendship between John Tames and Ernest Hart was continued between Charles Tames and Dawson Williams.

Sir Charles Tames was an old member of the British Medical Association, and served on its Central Council from 1900 to 1904. During the war he became chairman of the Norfolk and Norwich Hospital, and acted as inspector for the Norfolk Red Cross. He had been a vice-president of the Zoological Society of London, and was an honorary member of the American Dental Association.

Mr J G TURNER, FRCS, dental surgeon to the Royal Dental Hospital, sends this personal tribute.

The dental profession throughout the world will be profoundly moved by the death of Sir Charles Tames, and will turn in personal sympathy to Lady Tames in her grief. To most of us the loss is of a great intellect which has guided our thoughts and spurred us to seek knowledge with scrupulous care, but to some, perhaps now not many, the loss is more intimate. We remember the tall, spare, handsome figure, the somewhat shy greeting, the happy smile of recognition, the ready appreciation of a point well proved, and the glow of pride that Tames had agreed. Some of us have pictures of his painting (he exhibited at the Royal Academy under his Christian names, Charles Sissmore), some of us fished, and some of us shot with him and talked dogs. We all loved him as master and friend, and now we are the happier for a precious memory.

We are indebted to Dr CLIFFORD BEALE, consulting physician to the Royal Northern Hospital, for the following appreciation.

Of the large circle of friends prominent in medicine, art, and science, with whom the late Sir Charles Tames was associated in earlier life, but few are left. While others have borne witness to his services in the many undertakings in which he was interested, it may be

SIR CHARLES S. TOMES

permitted to a friend of over forty years' standing to recall some of the more personal charms of a many-sided character.

After his retirement from active practice in Cavendish Square he settled in Park Crescent, where he and Lady Tomes enjoyed, for many years, the pleasure of entertaining his numerous appreciative friends—professional, musical, and artistic—who delighted to discuss, if they did not always agree, with him the prominent subjects of the day. His scientific trend of thought, tempered by a strong vein of common sense, often proved valuable in counsel as well as interesting in social life. Himself a fine water-colour artist, he was always willing to listen to criticism of his own or others' work, even from the point of view of the man in the street. To those privileged to share his holidays in the North and elsewhere his keenness for sport with gun and fishing-rod was infectious, but for him there were no "off days." When others were inclined to rest from their self-imposed labours he would be away in search of a good subject for his next sketch.

His artistic provision led him in later years to seek out a home which should be a fit setting for the wealth of fine furniture, china, pictures, and other works of art which he had, from various sources, accumulated. Such a setting he found in Norfolk in the old moated house known as Mannington Hall, near Aylsham. There for many years he was able to entertain friends, to enjoy and constantly to enrich the fine old garden, to join in the sport for which the country is famous, becoming a keen shot himself, although his skill had been acquired only late in life, and employing spare time in a research into the history of Mannington Hall and its previous owners and occupants, of which he published an interesting account in pamphlet form. Upon the introduction of wireless telephony he at once entered into the study of its phenomena, and made countless experiments of his own with a view to improve reception until his failing powers during the last few weeks brought them to an end. An indefatigable worker, whether in science or in sport, he will always be remembered and honoured by those who knew him best as a modest leader, a sympathetic colleague, and a staunch friend.

[The photograph reproduced is by Elliott and Fry, London.]

W. M. BEAUMONT, M.R.C.S.,

Late Honorary Ophthalmic Surgeon, Bath War Hospital and to the Bath Eve Infirmary.

WE much regret to announce the sudden death in his consulting room while examining a patient at Bath, on October 18th, of Mr. W. M. Beaumont for many years a leading ophthalmic surgeon in the West of England.

William Mardon Beaumont was born in 1851, and studied at the Middlesex Hospital, in Aberdeen, and in Paris. He obtained the L.S.A. in 1874 and the diploma of M.R.C.S. Eng. in the following year. Subsequently he held resident appointments at the Middlesex Hospital as acting house-surgeon to the late Mr. J. W. Hulke and obstetric physician assistant for six months to the late Dr. A. W. Edis. He began his work in Bath as acting resident medical officer to the Royal Mineral Water Hospital, and subsequently devoted himself to ophthalmology. From 1888 to 1908 he served as honorary surgeon to the Bath Eve Infirmary, and during that time he built up a large private practice, and held office as vice-president of the Ophthalmological Society of the United Kingdom and of the South Western Ophthalmological Society. In 1896, when the British Medical Association met at Carlisle, he was honorary secretary of the Section of Ophthalmology, he was vice-president of the same Section at Leicester in 1905 and president when the Association met at Bath in 1925. He was for many years honorary secretary of the Bath and Bristol Branch of the Association and was appointed a member of the Railway Servants' Eyesight Committee at its formation in 1891.

During the war Mr. Beaumont's work as honorary surgeon to the Bath War Hospital took up nearly half his time. Throughout his career Mr. Beaumont contributed numerous papers on ophthalmic subjects to the medical press, several of which were published in our

columns. He devoted his spare time to antiquarian research and was a keen collector of pottery, brass, and old oak furniture. His collection of Brighthelm "blue dash" chargers is probably the finest in existence, and his antique furniture is of great interest.

The sudden nature of his death is undoubtedly what he desired, for amongst his papers has been found the following in his writing: "The one object of doctors seems to be to make a competence and then retire, after which they sit patiently on the platform and wait for the train to bear them to eternity. When my time comes may I rush to the station without time to think about the ticket or where I am going to and jump into the express as it is on the move."

Dr. SYLVSTER RICHMOND, whose death occurred at Greenhithe on May 21st in his eighty-eighth year, had only retired at the end of March from the post of medical officer of health for the Dartford rural district. He was probably at that time the oldest medical officer of health in England, and had completed fifty-eight years of service in that capacity. Dr. Richmond was born in Hampstead, and began his medical education at King's College, London, proceeding later to Edinburgh and Paris. In 1863 he obtained the diploma M.R.C.S. Eng., and two years later graduated M.D. Edin. His association with the public health service began in 1869, when he was appointed part-time medical officer to the Northallerton urban district and rural district councils, he remained there until 1885, when he accepted a similar position under the Dartford rural district council, and removed to that area, where he spent the remainder of his life. In 1912, when it was decided to place the work of the entire district under the control of a whole-time medical officer, Dr. Richmond was selected to fill the appointment. In the course of his long career at Dartford he witnessed a remarkable development in health matters, in housing, and in sanitation, and at the time of his retirement warm tributes to his services in this connection were made by the local authorities concerned. Until only two or three years ago he was a familiar figure throughout the extensive area under his charge, as he maintained his custom of visiting every district almost daily, travelling by cycle. He was also surgeon to the Dartford Cottage Hospital. Throughout his life he took a keen interest in the progress of medical science, he was a member of the Royal Medical Society of Edinburgh. At the funeral at Swanscombe many representatives of the local authorities and of various organizations were present.

We regret to announce the death of Dr. CHARLES WILLIAM SMEETON of Hovingham, Yorkshire, which occurred on October 13th, after a prolonged illness, in his sixty-fourth year. He received his medical education in Leeds, and obtained the diplomas M.R.C.S., L.R.C.P. in 1888. After holding a resident post at the Leeds General Infirmary he was associated for a time with the Leeds Dispensary, he subsequently removed to the Hovingham district some thirty years ago, and soon built up an extensive practice. At the outbreak of war in 1914 he volunteered for service abroad, but his offer was rejected on medical grounds, and he therefore undertook the task of commandant of the Red Cross Hospital at Hovingham Hall, conducting this institution single-handed and at the same time maintaining without assistance the work of his practice. In early life he had been, for ten years an officer in the Volunteer force, and during the war in addition to his hospital work he took command of a company of volunteers. Dr. Smeeton was a man of wide interests, and kept abreast of advances in various branches of science and general literature. He was a member of the British Association and of the British Medical Association. He married, in 1899, Ethel Isaacs, daughter of the late William Kendrell of Ness Hall, who survives him together with two sons and a daughter. The funeral at Hovingham on October 17th, was attended by almost every resident of the village and by a large number of representatives of the surrounding districts, a detachment from his

old Volunteer company acted as bearers Dr Noel O Lonsyth represented the York Medical Society and the British Medical Association A colleague writes Dr Smeeton represented the finest type of general practitioner He endeared himself to all, both rich and poor, by his kindness and devotion, not only as a physician, but both as friend and counsellor He was devoted to the people of the district and to the countryside, and he took great pleasure in all that the country has to offer He was a great example of the family doctor

Dr IAN DONALD MACKAY, who died suddenly on October 14th at his residence at Knaresborough, in his 67th year, had been in practice in that district for thirty-five years He received his medical education at the University of Edinburgh, graduating M.B., C.M. in 1886 After spending a few years in practice at Hornby, Lancashire, he removed to Knaresborough, where he became medical officer of health to the urban district council, he was also associated with the Poor Law service, and acted as medical officer to the Harrogate and Knaresborough Joint Isolation Hospital During the war he was on the staff of the Knaresborough Auxiliary Hospital Dr Mackay took a keen interest in medical affairs, and was a leading figure in the Harrogate Division of the British Medical Association From 1905 to 1923 he served upon the executive committee, in 1924-25 he was chairman of the Division, and in 1926 representative in the Representative Body of the Association He was for many years an office-bearer in the Knaresborough Parish Church Dr Mackay is survived by his wife and six daughters

The Services

TERRITORIAL DECORATION

THE Territorial Decoration has been conferred upon the following officers of the R.A.M.C. (T.F.) Majors A. J. Gibson and Hugh Forrest

No 14 STATIONARY HOSPITAL

THE ninth annual dinner of the medical officers of No 14 Stationary Hospital will be held on Friday, December 7th, at the Trocadero Restaurant, at 7.45 p.m., with Colonel C. R. Evans, D.S.O., in the chair

DEATHS IN THE SERVICES

Surgeon General Alexander Ferris Churchill, A.M.S. (ret.), died at Brentwood, Essex, on October 10th, aged 89 He was born in Dublin on June 14th, 1839, and was educated at Trinity College, Dublin, where he graduated as A.B. in 1860 and as M.B. in 1861, and in the school of the Irish College of Surgeons, whose licence he also took in 1861 Entering the army as assistant surgeon on March 31st, 1862, in the following year he was appointed to the 109th Foot, one of the East India Company's European regiments, which had just been taken over by the Crown, after the Mutiny The battalion subsequently, in 1881, became the 2nd battalion of the Prince of Wales's Leinster regiment, or Royal Canadians, and was disbanded after the great war In 1866 he was transferred to the 31st Foot, now the 1st battalion of the East Surrey regiment He reached administrative rank, as surgeon colonel, on October 27th, 1892, with thirty years service, became surgeon major general on May 7th 1896, and retired on June 14th, 1899 He served in the Sudan campaign of 1884-85, when he was in charge of Wady Halfa hospital, and received the Egyptian medal with a clasp, and the Khedive's bronze star

Flight Lieutenant Brien Lamburn Edwards, R.A.F.M.S., died in the British Military Hospital, Peshawar, India, on September 30th as the result of injuries sustained in a motor cycle accident, aged 25 He was born on July 13th, 1903, at Woolwich, Kent, the youngest (twin) son of Mr and Mrs Herbert Edwards, the family moved to Belfast in 1913 Flight Lieutenant Edwards received his medical education at the Queen's University, Belfast, where he graduated M.B., B.Ch., B.A.O. in June 1925 After temporary duties in Southport Infirmary and the East Suffolk Hospital, Ipswich, he joined the R.A.F.M.S. as a flying officer in October, 1925, and spent a year at Halton, Bucks In September, 1926, he left England for Iraq, where he served at Basrah, Kirkuk, and Hinaidi At Basrah he was sanitary officer for the whole area, also medical officer to an Indian regiment, and to the station headquarters and prison In October, 1927, he was promoted flight lieutenant, and shortly afterwards took a permanent commission in the

service Last summer he volunteered for service in India, and accordingly left Iraq in September He was posted to Peshawar, on the North West Frontier, and had been there only ten days when the accident which caused his death occurred He was buried with full military honours on the following evening in Tankie cemetery His untimely death is deplored by all who knew him, and his loss to the profession and the service is great He was a member of the Mesopotamia Branch of the British Medical Association

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

THE Faculty Board of Medicine has appointed Sir T. Gowland Hopkins, Dr Louis Cobbett and Mr Arthur Cook to be members of the M.D. Degree Committee until September next

Mr C. Warburton has been reappointed demonstrator in medical entomology

At a congregation held on October 27th the following medical degrees were conferred

M.D.—H. Wachter II F. Brewer
M.B. B.Ch.—H. M. Gilchrist W. R. Ashby J. W. Monro

Plusent Darwin Studentship in Mental Pathology

This studentship was founded in 1924 by the bequest of Mrs Plusent and Sir Horace and Lady Darwin for the promotion of research into any problem which may have a bearing on mental defects, diseases or disorders The studentship is of the annual value of about £200 and is tenable for three years in the first instance The student who may be of either sex and need not be a member of the University of Cambridge must engage in original research in Cambridge or elsewhere but may subject to the consent of the managers carry on educational or other work concurrently Further particulars may be obtained from the Registry of the University, and applications for appointment to the studentship should be sent before December 1st 1928 to the Secretary Plusent Darwin Studentship Psychological Laboratory, Cambridge Applicants should state their age and qualifications and the general nature of the problems in which they are interested and should give the date at which they would be prepared to begin work if appointed No testimonials are required but applicants should give the names of not more than three referees

UNIVERSITY OF LONDON

THE Senate has accepted with thanks the generous offer of Mr Geoffrey E. Dyson to make a further donation for the travelling studentship in oto-rhino-laryngology Regulations for the award of the studentship have been adopted

The Laura de Saliceto Studentship of £150 has been awarded to Dr A. P. Watson M.Sc. for the purpose of continuing investigations into the dietetic and other factors contributing to the genesis and development of experimentally induced tumours in animals

Sir Holburt Waring has been elected chairman of the Brown Animal Sanatory Institution Committee for 1928-29

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL

Three lectures in the history of medicine dealing with diphtheria, small pox and plague will be delivered by Dr Charles Sluiter at University College Hospital Medical School on Monday, November 12th 19th and 26th at 4.15 p.m. The lectures which will be illustrated by lantern slides, are open to all medical students of the University of London

UNIVERSITY OF MANCHESTER

THE Council have accepted the resignation of Dr W. M. Roberts lecturer in medicine and director of the Laboratory of Clinical Investigations and of Dr C. E. Branton demonstrator in human physiology

Mr F. W. Twillog, M.R.C.S. Eng., L.R.C.P. Lond., D.M.R.E. Camb., has been appointed lecturer in radiology

NATIONAL UNIVERSITY OF IRELAND

THE Dr Henry Hutchinson Stewart Medical Scholarships have been awarded to D. P. Kennedy (anatomy) and W. F. Whelton (physiology)

The following appointments have been made—At University College Cork Dr John C. Saunders professor of hygiene and public health At University College Galway Dr Edward N. MacDermott professor of therapeutics materia medica, and pharmacology, Dr Deula V. Morris, professor of midwifery and gynecology

The Dr Henry Hutchinson Stewart Scholarships in arts in medicine, and in mental and nervous diseases will be offered for competition in 1929

UNIVERSITY COLLEGE, DUBLIN

The following candidates have been approved at the examinations indicated

M.D.—F. J. Burke F. J. Murray Mental Diseases J. F. Smyth
M.B.—Ophthalmology K. B. McAreevy
M.B. B.Ch. B.A.O.—C. J. Shortall * J. Ryan * J. M. J. Maughan

Medical News.

THE annual dinner of past and present students of the School of Medicine, Leeds, will take place on Friday, November 9th, at the Hotel Metropole, Leeds, under the presidency of Dr C W Vining.

THE annual autumn dinner of the Glasgow University Club, London, will be held at the Froccadero Restaurant, Piccadilly, on Friday, November 23rd, at 7.30 p.m. The chair will be taken by Mr James Bonar, M.A., LL.D. Any Glasgow University men who, though not members of the club, desire to attend are requested to communicate with the hon. secretaries, 62, Harley House, N.W.1.

THE fifty second anniversary dinner of the Cambridge Graduates' Club of St Bartholomew's Hospital will be held on Wednesday, November 21st, at 7.30 p.m., at the May Fair Hotel, with Mr Frank Rose in the chair.

THE Lloyd Roberts Lecture on Faraday's Diary will be delivered by Sir William Bragg in the Barnes Hall of the Royal Society of Medicine, 1, Wimpole Street, on Thursday, November 29th, at 9.15 p.m. The president of the Society, Lord Dawson of Penn, will receive Fellows of the Society and guests at 8.30 p.m. The library will be open and a number of exhibits will be on view. Admission will be by ticket only, and applications should be addressed to the secretary of the Society.

At the meeting of the Hunterian Society, to be held at the Cutlers' Hall, Warwick Lane, E.C., on Monday, November 5th, at 9 p.m., there will be a discussion on "The Doctor on the Stage." The following have promised to take part: Dame Madge Kendall, Sir St. Clair Thomson, Lady Simson (Miss Lena Ashwell), Dr Harold Dearden, and Mr Ivor Back. Fellows of the Society may bring non-medical guests (including ladies) to the meeting.

DR E. P. CUMBERBATOR, medical officer in charge of the Electrical Department of St Bartholomew's Hospital will give two Chadwick public lectures on physiotherapy with special reference to medical electricity. The first lecture will be delivered at the house of the Medical Society of London, 11, Chandos Street, W.1, on Wednesday, November 21st, at 5.15 p.m., when Sir William Collins will preside. The second lecture will be given in the Guildhall, Bath, on November 22nd, at 8 p.m.

THE lecture courses arranged by the Royal Institution of Great Britain for the present session include two lectures on November 22nd and 29th by Dr E. D. Adrian, F.R.S., on the mechanism of the nerves, and two on December 6th and 13th by Sir Richard Paget, Bt., on human speech. The lectures will be given at 5.15 p.m. at 21, Albemarle Street, W.

At the meeting of the Pharmaceutical Society of Great Britain, to be held in the Lecture Theatre of the Society's House, 17, Bloomsbury Square, W.C. on Tuesday, November 13th, an address will be given by Mr C. J. S. Thompson, formerly curator of the Wellcome Historical Medical Museum, upon the apothecary and some curious materia medica of the seventeenth century, illustrated by specimens from the new additions to the society's museum. The president will take the chair at 8 p.m. and refreshments will be served after the meeting.

PRINCESS ARTHUR OF CONNAUGHT will open the new children's wing of the Wimbledon Hospital on Wednesday, November 21st, at 3 p.m.

The new Torbay Hospital will be opened on Saturday, November 17th, at 2.30 p.m. by Lord Midway of Flete, Lord Lieutenant of the County of Devon.

THE Joint Tuberculosis Council has arranged a post-graduate series of lectures and demonstrations on the pathology of tuberculosis and allied chest diseases. These will be held at the City of London Hospital for Diseases of the Heart and Lungs, Victoria Park, from Monday, November 26th to December 1st, including both mornings and afternoons, with the exception of the Saturday afternoon. The syllabus includes genito-urinary tuberculosis in the male, syphilis and tuberculosis, the investigation of the pre-tuberculous child, sputum examination, the early development of pulmonary tuberculosis, bronchiectasis and the various radiological and pathological investigations. The wards and various special departments of the hospital will be open to those taking part in the course. The fee is three guineas, and an application has been made to the Minister of Health to allow the course to rank for a grant. Further information may be obtained from Dr William Braud, The Larches, Farnham Royal Bucks.

THE Fellowship of Medicine and Post Graduate Medical Association announces that on Monday, November 5th, Mr Aleck Bourne will deliver a lecture entitled "When is the retroverted uterus a cause of symptoms?" at the Medical

Society, 11, Chandos Street, Cavendish Square, at 5 p.m. On the following Wednesday, at 2 p.m., Dr. Edward Williams will give a gynaecological clinical demonstration at Charing Cross Hospital, and on the same afternoon Dr. G. Carmichael Low will give a demonstration on "Recent work on blood diseases" at the Wellcome Museum of Modern Science, 33, Gordon Street, W.C.1, at 4 p.m. On Friday, November 9th, at 3 p.m., Mr. E. Gillespie will give a clinical demonstration in general surgery at the Prince of Wales's Hospital, Tottenham. Admission to these meetings is free. On Monday, November 5th, an afternoon course of clinical demonstrations in venereal disease, continuing for four weeks, will begin at the London Lock Hospital, Dean Street. Copies of syllabuses and information on all post-graduate work in London may be obtained from the secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1. The list of special courses for 1929 is now being printed; copies will be sent on application.

An exhibition of water colours of Italy, Spain, Holland, and Belgium, by Miss Mabel Spanton, daughter of the late Mr. W. D. Spanton, F.R.C.S., is now being held at Walker's Galleries, 118, New Bond Street, London, W.

DR. CORDELY BRADFORD, J.P., and Mrs. Bradford were honoured at a reception given on October 26th at Acoc's Green, Birmingham, to commemorate their golden wedding on June 4th, 1928. They were the recipients of an illuminated address, a gold salver, and a silver ten urn from many old friends among whom they had lived and worked for 43 years.

At the annual meeting of the National Council of Women, held at York last month, the following resolution about hospitals and women medical students was adopted: "That this council deprecates the proposal of certain London hospitals to discontinue the training of medical women, and urges that in the interests of the community a concerted demand should be made for women students both graduate and post-graduate, to have facilities for training as adequate and as efficient as are those that are open to men, including their appointment to paid and honorary posts in hospitals."

In celebration of the centenary of the *Spectator* a dinner was held at Claridge's Hotel on October 30th, and a commemorative number is to be published to day, November 3rd. A book, entitled *The Story of the Spectator, 1828-1928*, by Sir William Beach Thomas, which was published on October 25th, contains an interesting record of the history of the *Spectator*, and also sidelights on many events of the past 100 years.

The Council of the Royal Sanitary Institute has accepted the invitation of the Sheffield City Council to hold its fortieth Congress and Health Exhibition at Sheffield from July 13th to 20th, 1929. Earl Fitzwilliam will preside.

The Water Pollution Research Board of the Department of Scientific and Industrial Research issues periodically, in typescript, a summary of current literature bearing directly or indirectly on its activities. The issue for October consists of an author index to the first volume of these fasciculi. It may be consulted at the library of the British Medical Association.

In connexion with the celebration of the centenary of the Faculty of Medicine in the University of Cairo, arrangements have been made for a tour in the Mediterranean for medical practitioners, leaving Marseilles on December 1st and returning thither on January 5th. The places to be visited include Corsica, Sicily, Naples, Alexandria, Jerusalem (spending Christmas night at Bethlehem), Constantinople, Athens, Malta, Tunis, Constantine and Algiers. Further information may be obtained from Dr. Veillet, 43, Boulevard Raspail, Paris.

At the sixth International Congress of Historical Sciences recently held at Oslo, and presided over by Professor Halldan Koht, who is president of the Historical Society of Norway, the following papers of medical interest were read: medical considerations in favour of Glozel by Dr. Tricot-Royer of Antwerp, the observations of Pinel and his pupils on some abnormal personalities in the French Revolution by Drs. Laignel-Lavastine and J. Vinobon, medical instruction in the Middle Ages by Professor Karl Sndboff of Leipzig, social life of the leper in the old Duchy of Brabant by Dr. Tricot-Royer, and scientific medicine in Norway after the Middle Ages by Dr. Frederik Grøn of Oslo. The next congress will be held at Warsaw in 1933.

The tenth international medical post-graduate course was held at Carlsbad under the presidency of Dr. Edgar Ganz from September 23rd to 29th when the following papers, among others, were read: the treatment of gastric and duodenal ulcer by large doses of alkalis by Professor H. MnoBean of London, the relations of the female sexual functions to the liver by Professor H. Gngglsberg of Berne, changes in the liver of the constitution by Professor Sigerist of Leipzig, treatment of perniciosa anaemia by Professor G. Becker of Helsingfors, the cause of diminution of sugar tolerance in diabetes by Dr. G. Graham of London, eye

diseases and diabetes by Professor A. Elschuig of Prague, the treatment of obesity by Professor K. Glaessner of Vienna, failures in the surgical treatment of gall stones by Professor A. Jurasz of Posen, the pathology of puberty by Professor R. Neurath of Vienna, Wolf's disease and yellow fever by Professor Schiffrer of Amsterdam, and the treatment of tabes by Professor Wagner Jauregg of Vienna.

An account of the agitation in favour of wholemeal bread during the past fifty years has been published (Jarrold and Sons, Ltd., London and Norwich, price 6d.) by the Bread and Food Reform League under the title *Bread of Olden Days*. Miss May Yates, who founded the league in 1880, became an advocate of brown bread following her observation of the great strength of the Sicilian and Egyptian peasants, who subsisted chiefly on this diet. The author invokes the wisdom of Hippocrates, the endurance of the Spartans, and the success of the Romans as evidence of the virtue of brown bread, and describes white bread as an "impoverished, anemic product." There can thus be little doubt as to which side she takes in this controversy.

THE 1928 issue of the West African Medical Staff List shows a total personnel of 233, including 11 women. The list, as usual, contains three sections, giving the personnel for each grade and colony, and particulars of the qualifications and services of individual officers. Two issues of similar lists for the other colonies or groups of colonies which have medical services of sufficient numerical strength to warrant such a publication has long been overdue.

ACCORDING to a recent writer in the *Cronica Medico Quirurgical de la Habana* all Cuban children under 2 years of age in the rural population and 70 per cent. of those living in towns are infested with intestinal parasites.

As a memorial to her late husband, Dr. F. Melandri, who was for thirty-five years a member of the hospital staff, Mrs. Melandri has given £1,000 to the Italian Hospital, Queen Square, London, to provide a new x-ray installation.

Dr. LEREBoullet has been nominated successor of Professor Marfan in the chair of infantile hygiene, and Dr. Gougeon has succeeded Professor Jeannel in the chair of skin diseases and syphilis in the University of Paris.

THE third part (M-Q) of the Sale Catalogue published by L'Art Ancien, Lugano, of early books on medicine, material sciences, and alchemy has recently appeared. Each entry is accompanied by an explanatory note in English, and the text is freely interspersed with contemporary woodcuts.

Letters, Notes, and Answers.

QUERIES AND ANSWERS

ADMINISTRATION OF LIVER EXTRACT

"ANÆMIA" writes. In answer to W. (October 27th p. 777) may I say as an sufferer from pernicious anaemia, that in my opinion his patient will have to continue taking liver extract for the rest of his life? I have, by way of experiment reduced the daily dose of liver always with the same result—a reduction in the number of red cells. I think it is better to take too much liver than too little. Farther, I find I must stick to the

hydrochloric acid, dil., I take half a drachm three times a day. If this is left off the intestinal contents become very offensive. In addition, I take 15 grains of bismuth subnitrate three times a day as an intestinal antiseptic. I have tried many of the so-called intestinal antiseptics, I believe the bulk of them to be useless. "W." patient has a low proportion of haemoglobin, these should be about 80 to 85 per cent at least. I think more liver extract should be taken. I have a blood count every month, the information afforded is useful. A most important point in the examination is the size and shape of the red cells. There are two processes going on at the same time: the haemolysis and the defective manufacture of cells. If the red cells are large it may be safely presumed the blood factory is not in good working order. At the times when I have suffered a relapse, and have slipped back to say, 2 million "reds" this has been very noticeable. "W." does not say what preparation of liver extract his patient is taking. I have tried three or four, but prefer Armour's concentrated liquid liver extract, and I take nearly 1 oz each day. At my last blood count this month I had 5,220,000 reds, 85 per cent haemoglobin, index 0.82.

SEBORRHOEA OF THE SCALP

DR. I. B. McCANN (London, E.) writes: In seborrhoea of the scalp, with much dandruff I have been in the habit of prescribing an ointment of 10 grains each of sulphur and salicylic acid in 1 oz of soft paraffin. Though the results are satisfactory many patients after prolonged use find it greasy and too sticky for comfort. Can these two drugs (sulphur and salicylic acid) be put up in a more elegant fashion for use on the scalp even if more expensively? I prefer, if possible, to use sulphur and salicylic acid rather than a spirit lotion of hydrarg. perchlor and salicylic acid which is recommended as an alternative in most textbooks. Suggestions for an alternative treatment would also be welcome.

DELAYED MENSTRUATION

"A.E." writes: I have a patient, a girl clerk, aged 25 years who has never menstruated or, at the most, has only seen a slight stain. She has a good deal of adipose tissue especially on the legs and arms, and otherwise she is quite plump. She is in perfect health. She has been seen by very distinguished doctors. I can find nothing abnormal physically. Up to the time I saw her she has been three years on thyroid extract, eight months on hormotone and eight months on ovarian extract. Obviously it is no use doing what other people have done. Can any reader suggest some line of treatment or some further examination?

LETTERS, NOTES, ETC.

BLIND-DEAF CHILDREN

MR. A. J. STORY, general secretary National Institute for the Deaf (2 Bloomsbury Street, New Oxford Street, W.C.1), writes: This Institute is now considering the question of the early training of children who were born or have become, both blind and deaf. It is obvious that unless such unfortunate children are specially and entirely cared for from very early life their lapse into physical and mental incompetence is almost unavoidable. At the present time no distinctive provisions are available for the care of such young children. Single type institutions either for the blind or deaf, cannot receive them. We are anxious to get to know of the numbers of those doubly afflicted children who do not generally come under the notice of public authorities until an age at which the retardation due to silence and sightlessness, has become of grave importance and difficulty. It has been suggested that an appeal to doctors, nurses and those concerned with hospitals, baby welfare clinics, and other organizations dealing with childhood would be likely to help in tracing these blind and deaf children. May we therefore crave the assistance of your columns to request those of your readers who may know of cases of children of any age up to 8 years who are both blind and deaf, to help us by sending us full particulars of them?

"GREENED" POTATOES

DR. L. HARRIS LISTON (Middleton St. George Durham) writes with reference to the green colouring which appears on potatoes when exposed to light for a few days, and which is said to indicate the presence of a poisonous substance. He is informed by the Keeper of Botany at the Natural History Museum, South Kensington, that the poisonous element in the potato plant is the alkaloid solanine, which is present in all parts of the plant, though only to a very minute extent in the flesh of the tuber, there being more in the skin and the green parts. Dr. Harris Liston writes: Some persons cannot eat potatoes, being hypersensitive to very small quantities of this alkaloid. I and my servants have frequently eaten without ill effects, greened potatoes which have been skinned and boiled, and I have given such potatoes to pigs after boiling without any apparent bad symptoms. On the other hand the haulm of the plant, the seeds and sprouting and greened potatoes have caused serious symptoms and even deaths in live stock fed on such. During the war some soldiers in Berlin fed on such potatoes were badly affected with acute gastro-enteritis, their symptoms being pyrexia, headache, colic, diarrhoea, occasionally vomiting, and in several cases fainting while one had convulsions, most were drowsy and apathetic, but all recovered. I should be interested to hear if any readers of the *Journal* have observed such symptoms in people who have eaten these greened potatoes.

DEMENTIA PRAECOX AMONG PARSEES

DR. ARTHUR J. BROOK (North Queensberry) again joins issue with Lieut. Colonel Jagoe Shaw on the subject of dementia praecox among Parsees. In the course of a letter he states that "the Parsees seem not only to be afflicted with Westernization, but to have got it extra badly. Their schools appear modelled on strictly Western lines and one would naturally expect them to suffer from the chief diseases affecting Western civilization. Of these, early or precocious dementia is one of the most outstanding. Lieut. Colonel Jagoe Shaw tells us that the Parsees are particularly prone to this, and next to them the educated Hindus and Mohammedans; or rather, the boys of these two groups who have undergone the system of intensive cramming known to the Western world as education. Only the Parsees go in for consanguineous mating, whereas all of them go in for Western cramming methods. We Westerners are being decimated by dementia praecox, and there is no question of our marrying 'cousins,' except very rarely. Why not look for a factor existent in all groups, instead of only in ours?"

ACTINIC SKYSHINE MIRRORS

DR. E. C. MADDOX (Bournemouth) writes: Those who install "vita" glass windows in children's hospitals especially in the "rickets ward," might be glad to know how to render them most effective. Much of the actinic light which streams through a window is lost on the floor and furniture. The ceiling is the ideal receptive surface both for preserving the ultra violet radiation and for scattering it over the room. Without lessening the direct stream of light into the room an actinic mirror can be hinged to the foot of the window outside approximately horizontal, so as to cast additional skylight on to the ceiling. By an actinic mirror I mean one that reflects ultra violet radiation without any material loss. That is not the case of course, with ordinary glass which absorbs actinic light especially as the light has to pass twice through the substance of a mirror to reach the silvering and escape again. The suggestion is to silver "vita" glass and use it as a mirror with its edges and back painted with liquid celluloid or the like to preserve it from the weather. Metallic or even perhaps enamelled, mirrors would serve the same purpose. At night the mirror can be folded up

FIG 1.—Day

FIG 2.—Night.

against the lower part of the window, if desired to contribute to the warmth of the room by reflecting the escaping heat radiation back again. For simplicity's sake one direct and one reflected ray only are shown in the diagram. Inquiries about such glass mirrors can be made from the "Vita" Glass Marketing Board, Aldwyb House, W.C.2, and about metallic mirrors from Messrs. John Watts, 18 Soho Square, W.1. An inside mirror projecting horizontally from the foot of the window into a room or even a movable mirror table stood in the window would be better than none but besides occupying space it darkens some of the floor. The difference is this: that an inside mirror does not increase the amount of light entering the room but only diverts some of it, whereas the whole of the light contributed by an outside mirror is additional. Should a maximum effect be required both inside and outside mirrors could be employed. One word of caution may be advisable. Valuable though actinic mirrors would be in many children's nurseries their use for other ill-lit rooms in the house should be a matter of judgement depending on the inmates, for some weak eyes especially in elderly people and invalids, are not so tolerant of increased ultra violet radiation as normal eyes.

A WARNING

"M.D." sends a word of warning to fellow practitioners engaging dispenser bookkeepers. I have recently (he says) parted with a lady who came to me with excellent references and who turned out most unsatisfactorily. She has finally gone in circumstances which can, to say the least of it, only leave grave doubts as to her idea of mine and mine. It would seem that a little delay for the purpose of investigating references might prove time well spent.

VACANCIES.

NOTIFICATIONS of offices vacant in universities, medical colleges, and of vacant resident and other appointments at hospitals will be found at pages 48, 49, 50, 51, 54, 55, and 56 of our advertisement columns and advertisements as to partnerships, assistantships, and locum tenencies at pages 52 and 53.

A short summary of vacant posts notified in the advertisement columns appears in the Supplement at page 20.

Observations

ON

THE DIFFERENTIAL DIAGNOSIS AND TREATMENT OF CEREBRAL STATES CONSEQUENT UPON HEAD INJURIES *

BY

C P SYMONDS, M D, F R C P,

Physician in Charge of Department for Nervous Diseases,
Guy's Hospital Assistant Physician, National
Hospital Queen Square

THE subject of head injuries is treated, as a rule, in the textbooks of surgery rather than of medicine. It might seem, therefore, that in choosing it for our discussion we were encroaching upon surgical preserves. In practice, however, the proportion of cases of head injury which require immediate operative intervention is very small, and is limited to those in which a compound fracture calls for the obvious surgical toilet, or the rupture of a meningeal artery threatens life from cerebral compression. In so far as the latter is a cerebral state consequent upon head injury it might be included within the limits of our title, but in order that we may proceed to other and numerically more important aspects of our subject I shall propose to refer to it only in passing.

The various cranial nerve palsies which may result from fractures of the base are necessarily excluded as forming no part of a cerebral condition. Apart from the immediate surgical risks to which I have referred and the rare condition of subdural haematoma which I shall mention later, the severity of any injury to the head varies with the nature and amount of damage suffered by the brain at the moment of injury. Such damage may in itself prove fatal. When it does not there will result symptoms of cerebral disorder whose differential diagnosis and treatment may properly be considered as topics for neurological discussion. In attempting a brief description of these cerebral states I shall find it necessary to draw certain arbitrary lines of distinction.

CONCUSSION

I shall define concussion as a condition of subtotal cessation of cerebral function following immediately upon the injury, and lasting only a few moments, with subsequent complete recovery within twenty-four hours. During the initial stage the patient is completely unconscious and in a state of flaccid paralysis. In a severe case the respiratory and cardiac functions may hardly continue. In a few minutes recovery begins, the visceral reflexes are the first to return, and vomiting is common at this stage. The other cerebral functions recover more gradually, and there may be a phase of some hours during which consciousness is clouded. Following this again there may be complaint of headache and giddiness, but at the end of twenty-four hours in an uncomplicated case of concussion recovery should be complete and permanent.

The simplest explanation of concussion is that given by Trotter. The skull being in relation to traumatic force semi-clastic is deated or compressed by the blow, its contents being momentarily squeezed dry. The loss of consciousness and paralysis are due to sudden transient cerebral anaemia. The symptoms of the recovery stage are those of a gradual return of function in physiological sequence from the medullary centres upwards. The whole clinical syndrome being due to a temporary vascular embarrassment and independent of any structural lesion, recovery is complete and permanent.

CEREBRAL CONTUSION

Distinct from concussion, though often associated with it, is the condition of cerebral contusion. A fair idea of what is meant by this term may be obtained by anyone who will visualize the picture of cerebral damage in a case of fatal head injury. Apart from any direct laceration of the brain from compound fracture there is almost always to be seen in such a case diffuse bruising and

petechial haemorrhage, often with maximal intensity at the point of contrecoup. In such a case death has probably been due to direct or indirect damage to the medulla. In patients who recover with symptoms of cerebral damage we may reasonably suppose that some lesser degree of such bruising is present.

The symptoms of cerebral contusion depend upon two factors: first, the effect upon the intracranial pressure, and secondly, the precise situation of the lesion. To take the latter first, it is clear that the presence of paralysis, loss of sensation, or altered reflexes in a case of cerebral contusion must be an accident of localization. If the lesion involves the pyramidal cells or fibres an extensor plantar response will result, and so on. The focal signs of cerebral contusion, therefore, are those of cerebral disease generally. It may, however, be remarked at once that such focal signs are rarely to be detected, possibly because it is only in the relatively slight cases of contusion that recovery is possible. The effect upon the intracranial pressure, and hence upon the intracerebral circulation, will depend upon the amount of haemorrhage and exudation.

For purposes of clinical description I propose here to distinguish between a major and a minor degree of cerebral contusion, taking as the distinguishing feature of major contusion clouding of consciousness or stupor.

The General Symptoms of Major Contusion

The injury will almost always have been of such a nature and degree as to have caused concussion. The patient, having been completely unconscious for a few moments, partially regains his senses and passes into the state of stupor already described as a part of the clinical picture of severe concussion. Subsequently, instead of making that rapid progress towards a normal mental state which is characteristic of simple concussion, he remains stuporous, restless, and irritable. During the daytime, if left to himself, he is usually drowsy, lies curled up on his side, and resents interference. At night he is frequently noisy, hallucinated, and violent. The temperature and pulse rate, at first subnormal, are often raised.

This condition may persist for days or weeks, the tendency being towards gradual improvement, first manifested in the form of brief intervals of lucidity during the daytime, when the patient may ask where he is and for a few minutes behave and talk in a rational manner. On regaining his senses he is found to have an amnesia for the period of clouded consciousness. Such patients are often said to have been unconscious during this whole period, but it is important to distinguish between complete unconsciousness or coma and the condition of stupor or clouded consciousness which is characteristic of major contusion.

It has already been assumed that the general symptoms of cerebral contusion are due to increased intracranial pressure from capillary haemorrhage and transudation. Direct proof of this may be obtained by lumbar puncture, a manometer being employed to register the spinal fluid pressure. This is usually found to be well above the normal limit, and the fluid is often blood-stained, indicating the rupture of surface capillaries.

The effects of increased intracranial pressure upon cerebral function are well known, and there is no doubt that they are brought about by embarrassment of the intracerebral circulation. Here we have to consider three groups of blood vessels: the arteries with a high internal pressure, the capillaries with a much lower pressure, and the veins in which the pressure is lowest. It is clear, therefore, that when there is any increase of intracranial pressure, sufficient to embarrass the cerebral circulation, its first effect will be to compress and narrow the veins. Oozing from the capillaries may cause such venous compression, for the pressure in the capillaries is normally higher than that in the veins. But oozing from the capillaries cannot result in compression of the capillaries themselves—that is to say, the increased intracranial pressure due to cerebral contusion may be sufficient to embarrass the venous outflow and so cause a state of relative cerebral anaemia, but cannot reach the point of compressing the capillaries and

Made in opening a discussion in the Section of Mental Diseases and Neurology of the Annual Meeting of the British Medical Association in Cardiff 1928.

causing a state of cerebral anaemia. The symptoms of cerebral anaemia are coma and paralysis, of cerebral vaso-anaemia, stupor, irritability, and confusion. These latter constitute the true clinical picture of major contusion. The development of coma or paralysis must indicate some other and more formidable source of compression, such as arterial haemorrhage or subdural haematoma.

Having regained his full senses the patient, under the terms of our definition, passes out of the category of major contusion, and his further symptoms are those of minor contusion.

The General Symptoms of Minor Contusion

The injury may, or may not, have been such as to have caused concussion. It is possible for a glancing blow to bruise the brain, sometimes severely, without any loss of consciousness at the moment of injury.

The symptoms to be described may follow directly upon the injury, but more commonly develop after a latent interval of some hours, a day or two, or in certain cases after several weeks. Thus a patient who has been concussed may seem to have made a complete recovery from his concussion and yet later develop disabling symptoms. The three symptoms almost constantly complained of are headache, giddiness, and mental disability.

The headache is described in terms of pain rather than discomfort. Throbbing, shooting, splitting, are the words usually employed. At its worst it may be continuous with exacerbations. More commonly it is intermittent. If it has any fixed situation this is likely to be related to the site of the injury. One of the most characteristic features of this headache is a relation to alterations of posture. In most cases it is worse when the patient lies down. Thus it is experienced on going to bed, and may keep him awake during the early part of the night, and it is commonly present when he wakes in the morning. Often the patient will discover that one position in particular, lying with chin upward, to the right or to the left, is especially likely to cause or aggravate the headache. It may also be brought on or intensified by coughing, sneezing, and quick alterations of posture, as in stooping, or rising from the stooping posture. The other aggravating factors in order of their frequency and importance are mental stress, physical exertion, noise, bright light, a stuffy atmosphere, and thundery weather.

The giddiness is usually described as a general transient sense of unsteadiness. It is particularly related to sudden change of posture, so that the patient is, for instance, unable to stoop to lace his boots, or, if he does so, stoops and rises slowly and with caution. The changes from vertical to horizontal posture and vice versa occasioned by going to bed and rising are also apt to induce this symptom.

The mental complaints are of inability to concentrate, defective memory, indecision, loss of emotional control, and rapid fatigability of the mental processes. In severe cases this is associated with insomnia and nocturnal restlessness. There may be some clouding of consciousness at night time, the condition then approximating to that of major contusion.

The Focal Signs of Cerebral Contusion

As has already been stated, these are rarely encountered, and are to be regarded rather as accidents of localization than as of primary clinical importance. Their occasional presence, however, provides additional proof that the symptoms which have already been described have their origin in organic cerebral damage. As a reminder the association is of all the more value when it occurs in a case of minor contusion. I shall therefore quote briefly a single example.

In June 1924 a labourer, aged 39 presented himself with the characteristic complaints of minor contusion. The story was that six weeks previously, while he was at work a piece of steam piping fell on to the top of his head. He lost his sense of reckoning for a second but did not fall and saw the pipe dancing on the floor. He kept at his work and experienced no symptoms of importance until a week later when he commenced to have severe and disabling headaches. On examination he was found to have no physical signs with the important exception of an extensor

plantar reflex on the right side. The blow, which had been of a glancing nature, had been on the left side of his head near the vertex, and as nearly as could be judged over the upper end of the left precentral gyrus. He was treated over a period of three months and then returned to his work. At that time the right plantar response was flexor, but obtained less easily than on the left. He writes that at the present time he is well save for occasional headaches which occur at times of mental or physical strain or in thundery weather.

Apart from objective physical signs, there are certain symptoms which must be related to focal damage, amongst which permanent mental change and epilepsy are of importance.

Permanent mental deterioration to the point of necessitating institutional care would appear to be rare. Lesser degrees of impairment are by no means uncommon, especially after a history of major contusion. Thus in a series of 80 cases of head injury severe enough to necessitate hospital treatment, 18 patients interrogated one or more years after the injury complained of memory defect. Six of these had suffered from major contusion, in the terms of our definition.

Epileptic attacks may occur in the early stages of a major contusion and are usually of the Jacksonian variety. They are probably due to subarachnoid haemorrhage, and do not always portend a permanent liability to attacks. Of more serious significance are the attacks which develop after a latent interval of months or years. These are usually generalized seizures of major or minor character, and quite commonly persist. The frequency of epilepsy as a sequel of head injury is apt to be under-estimated through neglect of the latent interval. In a series of 20 cases (7 gunshot wounds, 13 civil accident) in which a family history of epilepsy could be excluded and there was a clear history of serious head injury preceding the first attack, the interval between the accident and the first attack was in 13 cases longer than two years. In 19 of the 20 cases the attacks were of a general nature. In 18 of the 20 cases in which the history of the earlier stages was adequate, the story was of a major cerebral contusion.

Cerebral abscess following a compound fracture and chronic subdural haematoma are two sequels of head injury which are likely to come within the view of the neurologist. Both are rare. The story of subdural haematoma is commonly that of a fall or blow upon the back or front of the head, with or without concussion. After a latent interval, usually of several weeks, the patient begins to complain of headaches and gradually develops other symptoms of increased intracranial pressure. Symptoms of mental disorder are often a prominent feature of this stage. Later stupor develops, and the final stage of coma and paralysis supervenes rather suddenly and proceeds rapidly to a fatal issue unless relieved.

Owing to the long latent interval and the trivial nature of the injury the diagnosis is sometimes missed because it has never been considered. Examination of the spinal fluid may be of value in a doubtful case, for this sometimes contains altered blood pigment and flakes of fibrin.

Finally, there is a considerable group of cases in which the disability which follows head injury is partly or entirely neurotic, based usually upon the problem of compensation. The symptom picture in these cases of so-called traumatic neurasthenia differs in no respect from that of any other anxiety neurosis, save that the patient's concern is chiefly with his head, and anxiety may be focused upon the question of damage to his brain.

DIFFERENTIAL DIAGNOSIS

The differential diagnosis of the several conditions I have described can best be reviewed by considering the problem as it may be encountered at varying intervals after the accident.

1 During the First Twenty-four Hours.—If the patient has been concussed it is impossible to make any comprehensive diagnosis of his condition at this period. The state of concussion masks what lies behind it. If after complete or partial recovery of consciousness the patient sinks again into a true coma or definite paralytic signs

develop, arterial haemorrhage is almost certainly present. If recovery is progressive and the patient is apparently normal at the end of twenty-four hours, major contusion may be excluded, but the symptoms of minor contusion may supervene. The absence of concussion does not exclude the possibility of the symptoms of minor contusion or subdural haematoma developing at a later stage.

2 After the first Twenty-four Hours.—If at this stage there is any clouding of consciousness, something more than simple concussion has occurred. A condition of stupor and irritability which persists, or shows a tendency towards improvement, indicates the presence of minor cerebral contusion. A lapse into coma or the development under observation of paralytic signs will provide evidence of an increase of intracranial pressure greater than can be accounted for by contusion alone, and should immediately arouse the suspicion either of a late arterial haemorrhage or the formation of a subdural haematoma. The patient who, at the end of twenty-four hours, has apparently recovered may yet develop symptoms of minor contusion, and the latent interval may amount to several weeks. It is especially likely to happen if the patient has been rested completely during these weeks and returns abruptly to his ordinary way of life. I have seen one or two striking examples in cases of multiple injury in which the contusion symptoms have developed only on the patient's discharge from hospital.

The symptoms of minor contusion are as a rule unassociated with any physical signs. They may need, therefore, to be distinguished from those of an anxiety neurosis. If they have developed from those of a major contusion—that is to say, if the patient has been stuporose for more than twenty-four hours after his injury—this fact should have considerable weight in favour of an organic basis. More difficult may be these cases in which the onset has been delayed.

The symptoms of true minor contusion, however, vary so little from one case to another that any physician who takes the trouble to elicit a full history will discover for himself a series of touchstones for the truth. Of particular importance are the character of the headaches and their relation to posture. The neurotic, as a rule, will describe his headache in terms of discomfort rather than of pain, it is continuous rather than intermittent, has no relation to posture, and is aggravated only by mental stress. The association of true contusion headache with giddiness also related to posture is a valuable point.

The mental symptoms are more difficult to evaluate, especially for one who has not known the patient before. It should be a rule in such cases to inquire for a family history of mental instability and to ascertain the patient's previous biographical record, with especial reference to nervous breakdowns. A patient who was sent to me for an insurance report with mental symptoms following a head injury admitted having had a similar nervous illness some years previously after he had accidentally swallowed his false teeth. Of the several physicians and surgeons who had examined him before none had elicited this important fact.

Retardation of the intellectual processes and a defective memory, especially for recent events, are valuable signs of organic cerebral damage, and would probably be discovered more often in these cases if formal tests for memory and retention were generally employed.

My impression is that the frequency of traumatic neuroses following head injury is a good deal exaggerated and that the minor mental symptoms so often encountered are mainly due to organic damage. They are, in fact, the mental symptoms of major contusion spread thin. The argument to the contrary, that such symptoms are commoner amongst workmen, is to my mind of no great weight. Mental stress is an important aggravating factor in the symptoms of true contusion, and one can hardly imagine a greater mental strain than that of a lawsuit far compensation hanging over a man who has nothing to show as evidence of his disability besides his own word.

In this connexion I would urge the importance of teaching the legal profession that the brain may be seriously damaged without any fracture of the skull,

without any objective physical signs, and occasionally in the absence of any history of concussion, and, conversely, that a fractured skull is in itself no proof of cerebral damage.

It would seem even that a fracture of the skull, if not fatal, may carry with it some degree of immunity from disabling after-effects. In the series of 80 cases to which I have already referred, the presence or absence of fracture was determined by x rays and clinical evidence in 72. Ten of these had fractures. At the time the inquiry was made—that is to say, one or more years after the accident—not one of these 10 was completely disabled, 7 were able to do full work and the remaining 3 light work. By comparison, of 61 cases without fracture, 7 were completely disabled, 28 were able to do light work only, and 26 full work. These figures suggest that, in so far as the traumatic force is expended in fracturing the skull, there is less available for lacerating the brain.

Of all the sequels of head injury, the differential diagnosis of subdural haematoma is the most difficult. My personal experience has been of 5 cases.

In one of these the diagnosis at first sight appeared to be that of a cerebral tumour. The patient was a young man with benign papilloedema and an extensor plantar response on one side. There was a story of a fall on the back of the head four months previously. The presence of xanthochromia and fibrin flakes in the spinal fluid led to a correct diagnosis.

In another case also presenting the signs of a cerebral tumour the correct diagnosis was made only at necropsy and no history of injury was ever obtained.

A third patient was admitted to hospital with hemiplegia under the diagnosis of cerebral thrombosis. The fact that the hemiplegia had taken several days to develop excited suspicion a history was obtained of a fall on the back of the head three months previously with slight concussion, and this led to a correct diagnosis.

In a fourth case increasingly severe headaches in a man with frontal sinus disease led to an operation for cerebral abscess. *Post mortem* a bilateral subdural haematoma was discovered, and the history of injury six weeks previously was obtained only after death.

The fifth case was that of a magistrate who was knocked down by a motor car, sustaining a black eye and contusions to his body and limbs. After ten days rest he returned to his work. Subsequently it was noticed that his judgement was faulty, he became irritable and was obsessed in a manner unlike himself about the question of compensation for his accident. He was thought to be suffering from traumatic neuroasthenia. It was not until two months after the injury that he somewhat suddenly became drowsy and developed the signs of a double hemiplegia. Exploratory craniotomy revealed a bilateral subdural haematoma.

TREATMENT

I shall not dwell upon the treatment of concussion further than to remark again that the indication for surgical intervention during the first twenty-four hours is a lapse into coma after a lucid interval or the development under observation of paralytic symptoms. At the end of this period, in a case of simple concussion, recovery will be complete. Minor contusion, however, may be latent at this stage. In every case of concussion, therefore, the patient or his friends should be warned of the liability to subsequent headaches, and he should be advised to return gradually to his normal mode of living. If headaches should develop he should be treated as a case of minor contusion.

In the treatment of a case of major contusion the first principle to be observed is that of complete rest, and in securing this expert nursing is essential. The patient should be disturbed and handled as little as possible. Food should be light and easily assimilable. Sedatives will often be necessary at night—paraldehyde in full doses is effective if the patient will take it, drugs of the medinal group are less satisfactory in that, given in sufficient doses to induce sleep, they sometimes tend to increase confusion on the following day. A similar objection applies to hyosine, which may sometimes be necessary in the management of a violent or noisy patient.

There are two means by which relief of intracranial pressure may be obtained during this stage, sometimes with excellent results. One is lumbar puncture. A manometer should be used, and the fluid—usually blood stained—

run off until the pressure is subnormal. If the procedure gives relief it may be repeated as necessary. The other measure which may be employed is the intravenous injection of hypertonic saline—50 to 100 c.c. of a 15 per cent solution is the dose usually given. The effect is to shrink the brain by absorption into the blood stream of its extravascular fluid contents. This effect is temporary, and the procedure may have to be repeated at intervals of two days. An alternative and simpler method of obtaining a similar result is to give a saturated solution of magnesium sulphate, 3 oz. in 6 oz. of water, by the rectum. This needs to be retained for half an hour if it is to be effective. In the later stages the treatment is the same as for minor contusion.

The symptoms of minor contusion should be treated in the first place by rest in bed. The position of choice should be decided by experiment. In most cases the patient is most comfortable when sitting propped up, and, if so, should be enabled to sleep in this position. Cases will be found, however, in which the patient will discover for himself some other position which is the optimum, and he should be encouraged to persist in it. He should be protected from bright light and noise, visitors should be excluded or strictly limited. An ordinary light diet may be given, but alcohol should be forbidden. A sufficient dose of magnesium sulphate should be given daily to secure a fluid evacuation. If the patient is at all inclined to be restless by day a bromide mixture should be given. Aspirin, 10 grains at need, may be administered for relief of headache, and chloral or medinal at night for sleeplessness. This regime should be maintained until the patient has been free from symptoms for a day or two. He should then get up for an hour or two each day and have more latitude in regard to visitors. In this way he should be permitted to return step by step to an ordinary quiet mode of living, being put back a stage should there be any tendency to relapse with increasing activity. When he is able to live in the ordinary way without symptoms he should be encouraged to subject himself to more stress by means of physical and mental exertion, in order that he may test his capacity for a fully active life. This is especially important in the case of a manual worker.

Treated by these means the majority of patients suffering from symptoms of minor contusion make complete recoveries. The outlook is not so good in cases where the only story has been that of major contusion.

I have notes of a series of 80 patients who have been under my care with symptoms of cerebral contusion and have replied to a recent inquiry as to their present state. This inquiry was limited to cases in which at least one year had elapsed since the accident. All were cases referred to me, either in hospital or private practice, on account of symptoms which had persisted despite the simpler methods of treatment. They represent, therefore, a group from which the mild and quickly recovering cases of minor contusion have been excluded.

Of these 80 patients, 18, or 22.5 per cent, stated that they had made a complete recovery.

Of 71 who were dependent for their livelihood on regular employment

- 33 (46.5 per cent) were able to return to full work
- 31 (43.5 per cent) were able to return to light work
- 7 (10.0 per cent) were totally incapacitated

These patients may be divided into those with major and those with minor contusion.

- Of 54 with minor contusion
 - 28 (52 per cent) were able to return to full work
 - 24 (44 per cent) were able to return to light work
 - 2 (4 per cent) were totally incapacitated

- Of 17 with major contusion
 - 5 (29.5 per cent) were able to return to full work
 - 7 (41 per cent) were able to return to light work
 - 5 (29.5 per cent) were totally incapacitated

These figures show that in the case of a major contusion the chances of the patient being able to return to his full work are less than one in three, and there is the same chance of total incapacity.

In cases of lesser injury, there is an even chance of the patient being able to return to full work, and a very small risk of total incapacity.

For purposes of obtaining these figures, the criterion taken for a diagnosis of major contusion was that the patient should have been in a state of unconsciousness, or partial unconsciousness, for more than twenty-four hours following the injury.

In cases of persistent contusion headache unreheved by medical treatment, surgical decompression has been advocated. I have seen this in one or two cases attended with considerable success, in others with none. The result may possibly depend upon a choice of the correct moment at which the procedure should be undertaken. I shall hope to hear more of this method of treatment from others with greater experience of it.

THE EFFECTS OF IRRADIATED ERGOSTEROL IN LARGE DOSES

BY

W. E. DIXON, M.A., M.D., F.R.S.,

AND

J. CLIFFORD HOYLE, M.B., B.S.,

ERNEST HART MEMORIAL SCHOLAR OF THE BRITISH MEDICAL
ASSOCIATION

(From the Pharmacological Laboratory, Cambridge.)

It is established that the presence of accessory food substances, or vitamins, is essential in the perfect diet. Observations are accumulating to show that when certain substances in a food are extracted and administered to animals in amounts out of proportion to the other constituents in that food poisonous symptoms may occur.¹ This has also been said to be true for the so-called vitamins. Excess of irradiated ergosterol—for example, when administered orally to rabbits and other animals—causes sickness and pathological changes.^{2,3} Mice died within twenty days after the administration of 1 mg. daily, rats and rabbits died within ten days with 10 mg. daily, and guinea-pigs died within thirty-six days after the administration of 50 mg. daily, whilst hens were immune. In those animals which died the characteristic *post-mortem* findings were an atrophic spleen, and extensive calcium deposits in the arterial walls, heart muscle, stomach walls, lungs, kidneys, and intercostal muscles, associated with secondary sclerosis of greater or less severity. It is obvious that changes of this character produced in so short a time are of a different order from the well-known arterio-sclerosis that can be produced in rabbits after feeding them with cholesterol for five to six months, or with non-irradiated ergosterol for two to three months.

The difference found by these workers between the therapeutic and toxic doses is considerable and leaves a wide margin of safety. It is important, however, to remember that their observations apply only to normal animals. We are still in the dark as to how far this ratio applies to man, and how far it may be modified in sickness or in initial vitamin deficiencies. The present observations were made to determine the effects of large doses of irradiated ergosterol on rats fed with a normal diet including an ample supply of vitamins A, B, and C. They demonstrate that grossly excessive amounts interfere with calcium metabolism to the extent that all the treated rats form calcium phosphate concretions in the urinary tract.

Experiment 1

Four litters each of four young rats weighing about 70 grams, were divided into four groups so that each group of four consisted of a pair from each of two litters. After ten days control observation on a bread and milk diet the ergosterol was given daily in addition. Group A received 2 mg. of irradiated ergosterol in 2 c.c. of arachis oil, and their litter mates in Group B 2 c.c. of the oil alone. Group C and Group D received 1 mg. of irradiated ergosterol in 1 c.c. of arachis oil, and 1 c.c. of the oil alone, respectively. The administration was oral by pipette, and was continued for forty days. All the rats remained in perfect condition.

Fig 1 shows the graphs of the average weights of the rats in the four groups, two experimental and two control. There is no significant difference between the curves for the control and experimental animals, the latter never lost weight at any time during the experiment. This does not conform with the findings of Kreitmair and Moll, who report a "slight loss of weight" in rats receiving 1 mg of

FIG 1.—Weight curves of the four groups of rats in Experiment 1. Group A—2 mg irradiated ergosterol and Group C—1 mg irradiated ergosterol daily for forty days. Groups B and D are the respective controls.

irradiated ergosterol daily. They found no pathological changes at *post-mortem* examination, however, and in this we agree, as we failed to detect abnormal naked-eye or microscopical changes in any tissue.

Experiment 2

This was devised to determine the effects of larger doses. Four groups each of four half-grown male albino rats of approximately similar weight were placed on a basal synthetic diet* modified for each group as shown in the following table.

TABLE I

	Group E	Group F	Group G	Group H
Basal diet ..	80	80	90	90
Cacao butter with 1% irradiated ergosterol†	20	—	10	—
Cacao butter† ..	—	20	—	10

Each rat was given, for a period of forty-five days, 15 grams daily of the mixed diet for its group. The rats were kept in separate wire cages raised from the floor, and the droppings collected every two days, so that any food lost through the floor of the cage could be separated from faeces and weighed, together with any left in the cage. In this way the exact quantity of food eaten and the dose of irradiated ergosterol taken daily could be calculated. Throughout the experiment all the animals were kept in one room under the same diurnal temperature changes. Weights were recorded twice weekly.

Fig 2 shows the weight curves of the four groups of animals, each curve representing the average weight of the rats in that group. One of the controls in Group H died on the twenty-eighth day of the experiment from intercurrent disease, and the weight curve for this group has therefore been based upon the average for the remaining three rats.

* The basal diet consisted of vitamin-free casein 23 per cent, potato starch 40 per cent, sugar 17 per cent, purified palm kernel oil 15 per cent, and salt mixture 5 per cent. The salt mixture was a modification of McCollum's containing in addition to the usual constituents 0.1 per cent KI and traces of NaF and MnSO₄. Every rat was given daily 0.3 c.c.m. of cod liver oil previously standardized for vitamin A, 0.5 c.c.m. of marmite extract and 0.2 c.c.m. of orange juice. Distilled water was supplied for drinking.

† These and the arachis oils used in the previous experiment were kindly supplied by the British Drug Houses Ltd. The ergosterol was irradiated with a mercury vapour lamp under exact control. The irradiation was effected in oily solution in the absence of oxygen for a period a little less than that required to give the maximum anti-rachitic property.

The rats of Group G, receiving an average daily dose of 11 mg of irradiated ergosterol, showed a steady increase in weight approximating to the controls in Group H. At no time, except to a slight extent during the first ten days, was any loss in weight noted. On the other hand, the animals in Group E, receiving 17 mg daily, showed a definite failure to gain weight at the same rate as the controls in Group F, indeed, except during the last few days of the experiment, their weights remained almost stationary. The average gain during the experimental period in Group D was 23 grams per rat, and in the controls in Group F 60.5 grams.

No definite symptoms were observed in the experimental rats, except occasional haematuria during the latter half of the experiment.

In Table II the *post-mortem* findings and the weight of the spleen and liver are given for each rat. None of the controls showed any pathological naked-eye lesions. The spleen and liver weights were similar except for the rats in Group E, in which the average spleen weight was some 20 per cent less than that of the controls. No pathological lesions were observed in any of the experimental rats except in the urinary tract. In every animal, with one exception, calculi were found in the bladder, ureters, or renal pelves, sometimes in all these situations. These calculi were yellowish in colour, of an irregularly rounded shape, and varied from a pin-point up to 4 mm in diameter. Details of the number found and their situation in individual rats are given in the table. Chemical examination showed them to be composed of calcium phosphate. Tests for oxalate, carbonate, triple phosphates, urates, xanthine, and cystin were negative.

In several cases the situation of the calculi had led to dilatation of the ureters and hydronephrosis on one or both sides. In two rats this was marked. Associated inflammatory changes were not present, the fluid above the obstruction was clear, and no pyelitis or cystitis was present in any instance. Where there was no considerable degree of hydronephrosis the kidneys on section showed a more or less well-marked yellow zone at the cortico-medullary junction. In the hydronephrotic kidneys the compression of the tissue masked this appearance.

FIG 2.—Weight curves of the four groups of rats in Experiment 2. Group E—17 mg irradiated ergosterol and Group G—11 mg irradiated ergosterol daily for forty-five days. Groups F and H are the respective controls.

Microscopical sections of the thoracic and abdominal aorta, heart muscle, lungs, stomach, liver, and spleen stained with haematoxylin and eosin, showed no pathological changes. Sections of the kidneys showed the typical appearances secondary to hydronephrosis when that condition was present—that is, dilatation of the tubules and capsular space of the glomeruli with atrophy of the lining cells and some proliferation of the interstitial tissue. When hydronephrosis was not present no such changes were found, the tissues in the zone of yellowish discoloration at the cortico-

TABLE II.—Showing the Weights of the Spleen and Liver and Post mortem Findings in Rats given Large Doses of Irradiated Ergosterol Daily for Forty-five Days

Groups	Average Daily Dose of Irradiated Ergosterol	Post mortem Findings			
		Weight of Spleen	Weight of Liver	No. of Calculi found and their Situation	Naked-eye Changes in Kidneys

medullary junction showed swollen cells, desquamated epithelium, and irregularly stained nuclei. No fatty changes were demonstrated. Frozen sections stained with Sudan III, or observed with the polarizing microscope, gave negative results. In all the animals sections of the organs were stained for insoluble phosphates and carbonates by Klotz's modification of von Kossa's method, using a 5 per cent aqueous solution of AgNO_3 , and staining for four hours. No evidence of calcium deposition was found. In one case the sections had included a small calculus lying in the renal papilla.

DISCUSSION

Several observers have described the occurrence of urinary calculi in rats which were fed on defective diets (refs. 4 to 9) but from the evidence available it is difficult to assess with confidence the precise cause of the condition. In most of the experiments no details of diets are given. In McCarrison's work⁹ the diet was defective in several ways, so that the formation of calculi cannot be ascribed to any one constituent. In all the observations, however, one constant feature was a lack of fat-soluble vitamins. Much evidence has accumulated to show that animals fed on a diet defective in vitamin A are particularly susceptible to low-grade infections such as xerophthalmia and respiratory disorders (refs. 10 to 14). Calcium deposits are a frequent sequel to chronic infections, especially those which cause the death of tissues such as tuberculosis. This is especially the case in the urinary tract, where infection readily leads to urolithiasis. Osborne and Mendel suggested that the calculi formation in their experiments was due to infection following deficiency of vitamin A. In several of the subsequent papers on calculi formation the authors

do not state whether infection of the urinary tract was found or not, in others the writers state that though occurring in a majority of instances it was absent in others.

In the present experiments lack of vitamin A was certainly not the explanation of the calculi formation. All the animals were given a correct diet, with an adequate allowance of vitamins A, B, C, and D. The control animals were in every way normal, and infection of the urinary tract was present in no case, control or experimental. In these experiments the origin of the stones must be entirely different from that of those previously described, in that it must be due to excess of irradiated ergosterol. It is known that this substance influences the reaction of the intestinal contents (refs. 15 to 17), and direct evidence exists to show that the reaction is a controlling factor in the absorption of calcium and phosphate from the gut.^{21, 22} In this way it is probable that irradiated ergosterol facilitates the absorption of these substances. All this evidence suggests that calculi formation may accrue by the excretion from the kidney of large amounts of calcium and phosphate than can be held in solution by the urine, and this we believe is the explanation of the present observations.

The amounts of irradiated ergosterol necessary to cause urinary calculi were so large that the condition has obviously little clinical importance. The German observers, however, obtained much more marked changes with smaller doses, and if their experiments are valid then an excess of vitamin D may not be without clinical interest. The diets used by the German workers for their rats are not given, and some irregularity here may have exaggerated the differences in the results, although they do not describe

Further work on the urinary excretion of calcium and phosphate is in progress.

the presence of calculi Green and Mellanby³ have recently substantiated the frequent occurrence of calculi in rats on diets deficient in vitamin A, and have shown that when ergot, which is rich in vitamin D, is given along with this diet the incidence of calculi rises. In other words, with a satisfactory diet containing ample accessory factors, stone formation is difficult to produce with a very large excess of irradiated ergosterol, whereas when the diet is defective stone formation is relatively easy to produce, and it may well be that a dose of irradiated ergosterol which is without effect on a well-nourished animal may give rise to urinary calculi in one which is badly nourished. The natives of certain tropical countries are known to live on diets which are often defective in several ways, particularly in regard to vitamins, and it is suggested that they must manufacture large amounts of active ergosterol in their widely exposed epidermis, since the solar rays have high actinic value. The two factors, perhaps, are sufficient to cause the phosphatic concretions in the urinary tract which are known to occur with great frequency among such populations.²⁴

The results found by the German workers have a much more serious significance than those recorded here. The Germans claim their results to be a "hypervitaminosis." It is evident, however, that our failure to confirm their work throws doubt on this assumption, and suggests that some independent toxic factor complicated their experiments. They do not state any details about their method of irradiating ergosterol. This may well be a crucial factor, particularly as regards the solvent used during irradiation, and there is evidence to show that when irradiated in alcohol the product is toxic.

CONCLUSIONS

1 Irradiated ergosterol administered by the mouth in very large doses causes the formation of urinary calculi.

2 It is suggested that this is dependent upon an increased absorption of calcium and phosphate from the gut and their excretion by the kidneys.

3 No confirmation has been obtained of the pathological changes found to occur with similar doses by certain German observers.

The present work was done during the tenure by one of us (J. C. H.) of the Ernest Hart Memorial Scholarship of the British Medical Association.

An Address

OF

THE INFLUENCE OF INDUSTRIAL POISONS UPON THE DIFFERENT ORGANS *

BY

SIR THOMAS OLIVER, M.D., LL.D., F.R.C.P.,

CONSULTING PHYSICIAN TO THE ROYAL VICTORIA INFIRMARY, NEWCASTLE UPON TYNE, VICE-CHANCELLOR OF THE UNIVERSITY OF DURHAM

To describe with exactitude the influence of industrial poisons upon the human body is a difficult task, for much depends upon the length of the exposure to the poison and its quantity, the state of health of the workers at the time, and their individual susceptibility. Nor can I do more than cover four or five of the industrial poisons.

LEAD

Taking lead compounds as an illustration, there is the fact that some workmen acquire a degree of immunity to them, while others are liable to become affected only at certain periods. Much depends upon the rate of absorption of the poison into the system. Again, there is the question of age, experience having shown that young adults are more liable to become affected. There is, too, a personal and familial idiosyncrasy towards such a metal as lead. Before the interdict in Great Britain of female labour in the dangerous processes of white lead manufacture I frequently found members of certain families peculiarly liable to become affected, while those of other families escaped, and, if anything, that females were more readily adversely influenced by lead than males. In some instances so great was the personal idiosyncrasy that on one occasion a healthy girl, 18 years of age, after working in a white lead factory for six weeks, died from saturnine encephalopathy.

Notwithstanding the circumstances I have alluded to, there are facts of a general character which can be applied in such a manner as the title of this address suggests. When a poison has been absorbed and has circulated in the blood it might be expected that the whole body would more or less suffer simultaneously, but experience shows that certain organs and tissues exercise a selective influence

upon some poisons and not upon others. A distinction must be made between acute and chronic forms of industrial poisoning. There is the opinion that those tissues of the body which are the last to be developed, and therefore the more delicately organized, are less resistant, hence the rapidity of the effects of alcohol upon the higher nerve centres in the brain. While the nervous system is not free from the harmful influences of lead, many recent research workers regard the blood and the haemopoietic system as the anatomical elements earliest affected by lead—those bodily units, in fact, which are formed and function in the early stages of embryonic development, and which, therefore, ought to be the most stable. It is an interesting circumstance that while the blood and blood-making organs are readily influenced by lead, yet in the blood very little of the metal is found, even while the internal organs may contain it in considerable quantity. Although the blood may show physical and chemical changes due to the influence of lead, it has only slight retentive power upon the metal, possibly, because the blood is ever changing and therefore rejuvenating itself, its corpuscles are short-lived, also that it is constantly eliminating the poison, while in the tissues generally physico-chemical changes are less rapid, and there is therefore greater opportunity for the metal to become more firmly linked to the cellular constituents.

The types of industrial poisoning which have the greatest interest for us are those where the amount of toxin received daily into the system is small, where elimination falls short of absorption, and where, therefore, poisoning is slowly induced. In many of these cases symptoms of toxic action may not arise for several years—so slowly, in fact, do the symptoms appear that the individual is not aware of his condition until some change occurs in his metabolism or he is attacked by some minor ailment.

It is now several years since I remarked upon the storage of lead in a rather insoluble form in the body, also to the absence of symptoms until there have occurred chemical changes in the liquor sanguinis and in the fluids bathing the tissues whereby the deposited lead becomes soluble, thus favouring its reabsorption into the circulation. To this subject, and the early harmful effects of lead upon the blood, Anst and his co-workers in Harvard University have given close attention, as also have Kehoe and Thannmann of the University of Cincinnati, and P. Schmidt of Halle, who hold, like many other physicians, that by a microscopical

* Delivered before the Fifth International Congress for Industrial Accidents and Occupations, Budapest, September 3rd, 1928.

examination of the blood of lead workers plumbism may be detected before the symptoms develop, and when, therefore, it is possible for further trouble to be averted. The relation of the blood to poisons passing through it are of a twofold character: the blood may be little affected by them, or physico-chemical changes may be induced in it which affect its efficiency as an oxygenating and nutritive medium.

So far I have dealt mainly with lead, principally because, apart from iron and steel, lead is the metal which is most widely used in the industries, also, because it has been the occasion of much ill health among the workers. Most of its salts, too, have the power of precipitating proteins, as observed on mucous membranes, thereby exercising a protective influence compared with the corrosive effects produced by several other industrial poisons. Absorption of the metal is slow, so that time and opportunity are given for lengthened reaction to take place between the poison and the animal tissues.

Industrially, lead poisoning is seldom acute. When large doses of lead acetate have been swallowed by a healthy person the symptoms which follow are less the result of absorption of the metal than of the local effects of the lead compound upon the stomach and intestine. The intravenous injection of a neutral lead salt precipitates the proteins of the blood and may cause embolism. Harnack found, in injecting lead-triethyl into the veins of animals, that it became decomposed in the tissues and gave rise to symptoms of plumbism. Lead intravenously introduced into dogs causes pæsis and paralysis, diarrhoea, colic, tremors, and convulsions. Harnack considered the diarrhoea to be the result of violent contraction of the intestinal wall, and that this persisted even when no peristaltic wave was passing. In my own experiments I found after death discontinuous portions of the small intestine, over lengths of three or four inches, so firmly contracted as to have obliterated the intestinal canal, and which appeared to me to have been rather the cause and explanation of the colic.

In order to ascertain the effects of lead upon the heart and blood pressure Sir Robert Bolam and I carried out a series of experiments in which we introduced a solution of a lead salt directly into the blood stream. Lead is a protoplasmic poison, it acts specially upon highly developed tissues, such as muscle and nerve, and also upon the blood. Without entering into details too closely, we found that the injection of 5 c.c. of a 1 per cent solution of lead nitrate was followed shortly afterwards by a fall of blood pressure, the same result was observed after the injection of 5 c.c. of a 2 per cent solution of lead nitrate, but in each instance the fall of blood pressure was quickly recovered from. The injection of 10 c.c. of a 10 per cent solution caused a marked fall of blood pressure, and on repeating the injection shortly afterwards there occurred a rapid declension of the blood pressure and stoppage of the beat of the heart, respiration meanwhile continuing. After an interval of a few minutes the heart recovered its beats, feebly at first, then, becoming stronger, they gradually reached the normal. With a further injection of half the quantity both the heart's beat and respiration gradually ceased. At the necropsy twenty-four hours afterwards the urine was found to be free from albumin, the wall of the heart, especially the right ventricle, was soft, the lungs were healthy, the abdominal veins tense and full. The kidneys appeared to be congested, the liver was dark, and the surface of the brain congested, although the internal tissue was pale. Other experiments, whether upon a dog or rabbit, gave similar results—namely, a general fall of the blood pressure. The effect of lead salts carried directly into the blood stream was apparently mainly upon the heart and vasomotor centre. Respiration was not directly affected by lead; it apparently became indirectly affected through the fall of blood pressure.

There is a general opinion that workers in the lead industries in course of time develop structural changes in their arteries and have a high blood pressure. The numerous deaths among them from cerebral hæmorrhage lend weight to the supposition, but as the kidneys are prone to become diseased, inefficiency of these organs as a contributory cause cannot be ignored. We cannot quite place patients in whom symptoms of plumbism appear early in the same

category along with those who are the subjects of chronic plumbism, for, in the latter, structural changes have probably developed in the internal organs. A single dose of lead hardly ever gives rise to symptoms, but if small quantities are repeatedly passed into the system through the alimentary canal or the lungs chronic plumbism develops, indicating that absorption has taken place, and that possibly some of the lead may have become locked up in the tissues, from which it will be only slowly eliminated. The internal organs in which after death the metal is found are the liver, kidneys, brain, and bones. Lead is eliminated by the kidneys, the intestinal epithelium, the mammary secretion, and the saliva. Any effect, therefore, produced by lead is not so much due to the amount of poison circulating in the blood at a particular time, nor to its deposition in the tissues, but, as Stannb suggested, to the summation of the injuries inflicted by its recurrent presence in the blood in infinitesimal quantities.

ARSENIC

In Great Britain, since harmless pigments have replaced Scheele's green (arsenite of copper), also Schweinfurth's green (arsenite and acetate of copper), in wall papers and paints, industrial arsenical poisoning has considerably declined. In 1900 there were reported to the Home Office 22 cases of industrial poisoning due to arsenic with 3 deaths, in 1926 5 cases with 3 deaths, and in 1927 3 cases with one death. Pure arsenic is insoluble in water, so that if swallowed it passes through the gastro-intestinal canal practically unchanged, although very minute portions might be converted into arsenious acid in the stomach and intestines. The symptoms caused by its compounds are less due to the metal itself than to the ions of arsenious acid, which if swallowed in fairly large doses cause violent abdominal pain, vomiting and watery diarrhoea, muscular cramp, collapse, feeble pulse, coma, and death. It matters little the channel by which arsenic gains entrance into the body, for the same gastro-intestinal events arise, showing that the mucous membrane of the alimentary tract is the medium whereby it is eliminated, although the metal may be found in the hair and also be a cause of pigmentation of the skin, as has been observed in chorea patients treated by increasing doses of liquor arsenicalis. Taken in medium doses over a varying length of time it produces peripheral neuritis, as occurred in epidemic form in England a few years ago in beer-drinkers whose liquor contained the poison, which was traced to the required glucose having been obtained by sulphuric acid methods from iron pyrites containing arsenic. Yet, even to such a dangerous metal as arsenic, tolerance can be established by taking graduated quantities, as was shown a few years ago by the arsenic-eating peasantry of Styria and Tyrol. These hillmen, swallowing arsenic in small but increasing doses, stated that it enabled them to climb the mountains with less effort, and that it improved their respiratory powers, while their womenfolk believed that it improved their complexion. The practice did not appear to exercise any harmful influence upon these country people, for they lived to a great age without exhibiting any signs of disease or of ill health.

The worst effects of arsenic as an industrial poison which I have seen have been not so much upon the internal organs as upon the skin. This was especially so upon the hands and fingers, also upon the external reproductive organs, of men engaged in mixing colours, of which Scheele's green formed a large constituent. The skin of the fingers and hands was ulcerated, often down to the bone, the ulcers were angry looking and painful.

The presence of arsenic in soot is regarded as the cause of chimney-sweep's cancer, also of malignant growths upon the hands of gardeners who use soot for potting and other purposes. Combined with hydrogen, a dangerous and subtle form of poison is produced. Arseniuretted hydrogen when inhaled rapidly induces sickness and vomiting, followed several hours afterwards by jaundice and hæmoglobinuria or hæmaturia. The breaking down of the red blood corpuscles is so complete that the hæmoglobin becomes incapable of carrying on its respiratory function while the liver and kidneys are severely taxed in regard to the elimination of the disintegrated products.

MERCURY

In the industries subacute and chronic forms of mercurial poisoning may be met with. Of the organs primarily affected in the less acute forms of poisoning the salivary glands call for mention. They are stimulated to great activity, the gums are swollen, the teeth become loose, the breath fetid, and on the buccal mucous membrane small ulcers may be observed. The submaxillary glands become enlarged, mastication is difficult and painful, there are diarrhoea and loss of appetite, followed by pains in joints and limbs. In addition to the inordinate flow of saliva there are muscular tremors, at first mainly of the muscles of the face and hands, but if the individual continues to follow his occupation the tremors become general and render him helpless. In the company of Dr. Ghiglioli of Turin I had the opportunity a few years ago of visiting the mercury mines on Mont Amata in Italy, and of witnessing unusual signs and symptoms which are probably confined to smelters alone. Several of the men were so much affected through inhaling the fumes of the metal that if, during the act of walking—and this generally with a staggering gait—they were called upon suddenly to stop, they could not immediately arrest their progress. In attempting to do so they were either precipitated forwards, or swayed excitedly forward and backwards. There might be no tremor observable when the body was at rest but tremors soon showed themselves equal in range to those observed in disseminated sclerosis when slight effort was made. These movements were very pronounced, as when, for example, a glass containing liquid was given them from which to drink. So violent may the movements subsequently become, or so extreme the muscular paresis or paralysis, that many of the affected smelters are ultimately rendered completely helpless—they can neither feed nor dress themselves. Workers in mercurial compounds not infrequently have albuminuria.

PHOSPHORUS

It is not inappropriate that here in the capital of Hungary I should allude to industrial phosphorus poisoning for it was in this country a few years ago that its Government and members of the medical profession gave me opportunities of studying problems of phosphorus necrosis in lucifer-match makers. Here, as in all progressive countries, there is no longer industrial phosphorus poisoning. As far back as 1870 the sufferings of lucifer-match makers had attracted public attention. In 1872 Finland, in 1874 Denmark, in 1887 France, in 1898 Switzerland and in 1901 the Netherlands, had prohibited the use of white phosphorus, but the regulations had not the desired effect, nor was any united and organized effort made to secure this object until Switzerland, in 1906, invited the various countries to attend a meeting in Berne, known as the Berne Convention, at which the countries represented unanimously agreed to the prohibition of the dangerous metalloids. French chemists had found in phosphorus sesquisulphide a safe substitute for the dangerous form, and where or it has been used phosphorus necrosis has disappeared as an industrial disease. To France therefore, belongs the credit of having made possible the replacement of a harmful by a harmless chemical agent in this important industry. It was not, however, until 1919 that India and Japan joined the Convention, but even as late as 1923 China still remained outside the Convention and so in China years after other countries had shown how the manufacture of lucifer matches could be made a harmless industry, workers in the factories of the far Orient were still the subjects of phosphorus necrosis and of the ill health attendant thereupon. At the date just referred to there were at least twenty-eight match factories in China which were known to be using white phosphorus. My thanks are due to the Commissioner of Public Health Shanghai Municipal Council, and to Dr. Noel Davis and Dr. Martland for the opportunity of knowing that in China until the last three years there were still cases of phosphorus necrosis occurring among the workers, long after the malady had ceased in other countries. In 1925 according to the *China Journal of Science and Arts* of February and March of that year, there were 15,000 persons employed

in lucifer-match factories using white phosphorus. During the previous five years there had occurred from 20 to 30 cases of phosphorus necrosis, but there were many more than these. Even in 1924, while China was discussing the advisability of prohibiting white phosphorus, three patients with necrosis of the jawbone were admitted into St. Luke's Hospital, and during the previous three years 5 cases were treated in the Pekin Hospital. In January, 1925, China definitely prohibited the use of the harmful material, so that with her entrance into the Berne Convention there is now the probability of the disappearance of a painful occupational malady in the Far East.

RADIO-ACTIVE SUBSTANCES AND THE HEALTH OF THE WORKERS

Three years ago my attention was drawn by Dr. Frederick L. Hoffman, the well-known American statistician, to the occurrence of necrosis of the jawbone and of aplastic anaemia in young women engaged in painting numerals on illuminated match and clock dials. There had occurred 6 deaths, and there had been reported 7 cases of serious disease. Radium salts formed the basis of the luminous material, but one of the manufacturing firms used mesothorium, a substance which ranks next to radium, and, being an isotope of radium, it is chemically identical with and even slightly more active than it, although mesothorium decays 250 times more rapidly than radium. When zinc sulphide is added to the paste used for painting the dials it is rendered luminous by the radio-active substances present, and as mesothorium is cheaper than radium, and its luminosity greater, it found great acceptance by employers as a substitute. In one factory wherein there had occurred among the workers cases of necrosis of the jawbone, the luminous paint contained zinc sulphide rendered luminous by activation with 20 per cent of radium and 80 per cent of mesothorium, in another factory the luminous powder contained radium bromide and zinc sulphide. The powder is mixed with gum arabic dissolved in water, glycerin, and a small quantity of formaldehyde, or it may be simply mixed with oil. In painting the numerals on the dials the girls were in the habit of pointing with their lips the camel-hair brushes, and although each of the workers was given a bottle of distilled water* in which to wash the brush before putting it between the lips, they disregarded the hygienic provision. The girls had followed the occupation for three years or more. Exposure to large amounts of radio-active material is followed by changes in the blood of the workers, microscopical examination revealing a distinct reduction in the number of polymorphonuclear and lymphatic corpuscles. The leucopenia is pronounced. There is also a degree of anaemia suggesting a diminished output of red blood corpuscles from the bone marrow. The colour index however, remains high. Many of the women in this occupation complained of headache, malaise, tiredness and a sense of the need of more sleep, nervous irritability, and disordered menstruation, but the morbid condition which specially attracted attention was necrosis of the jawbone in five women of whom three died. For information of these cases we are indebted to a report furnished by Dr. Cecil K. Dinker, Dr. Martland, and others.

The necrosis differs from the infective processes of the jawbone following extraction of teeth, or that due to tuberculosis, it closely resembles the diseased bone found in phosphorus poisoning. By the time Hoffman studied the subject from the technical point of view five girls had died. An interesting point in regard to exposure to radio-active compounds is that the disease which develops may be latent for a few years before showing its destructive effects upon the teeth and jawbone. From the onset these agents affect the blood and blood-making organs, in small doses they temporarily increase the numbers of red and white corpuscles of the blood, followed subsequently, if the exposure continues by a destruction of the white and by a diminished production of the red corpuscles, hence the consequent anaemia.

In September of last year it was my privilege when in the United States, to examine with Dr. Hoffman five young

* *Monthly Labour Review* U.S. Department of Labour May 1925 p. 20

women dial painters who were suffering from the effects of radiation. One of the women had lost a sister, aged 21, from necrosis of the jawbone, while another had lost her companion from the same cause. Three of the five women could hardly walk, nor could they sit properly on a chair except in a slanting position with their limbs fully extended. There were osteitis and strong adhesive fibrositis of the hip-joints, so that the limbs could not be abducted. In three of the women there could be seen and felt small areas of exposed portions of the lower jawbone. Not one of the women was in good health, so that thus at a comparatively early age they were crippled for life.

THE BLOOD IN INDUSTRIAL POISONING

This subject is discussed in an interesting and exhaustive paper by Professor P. Schmidt of Halle*. He has so completely covered the field of inquiry, and brought to bear upon it experience gained by careful research, that the paper may be regarded as one of the fullest expositions of this important subject, as also of the intricate problems to which it gives rise. I can add nothing to what he has written, but gratefully acknowledge the value of the views he has expressed. Opinions are still divided as to the form some metallic poisons assume when, after absorption, they circulate in the blood and become deposited in the tissues. Taking lead as an illustration, it was formerly believed that it was deposited as albuminate. It may possibly be in a colloidal state combined with the albumin or acids, either as a salt of a fatty acid or of phosphoric acid. As regards the action of lead upon blood plasma, Kobert maintains that there is "a displacement of the fractions of albumin towards the side of greater dispersion with an increase of fibrinogen." The haemolytic processes allow of these displacements, so that the "free haemoglobin becomes changed in the liver to globulin."

In the haemolysis induced by poisons the destruction of the red corpuscles may probably depend on the reaction of the poison with "the lipoids of the supporting substance of the cell stroma," hence the presence within the red blood corpuscles of minute spherical masses of haemoglobin, the so-called "internal haemoglobinaemic bodies" of Ehrlich and Lindenthal. As Schmidt properly reminds us, some metallic poisons, while causing a discharge of haemoglobin from the stroma of the red blood corpuscles, also change the oxyhaemoglobin into methaemoglobin, whereby the haemoglobin loses its respiratory function. The blood in these circumstances may assume a dark brown colour, the lips of the individual may become cyanosed and the urine brown. So far as lead is concerned, Aub and his fellow workers take the view that the haemolysis is due to a change in the elasticity of the red blood corpuscle as a result of the formation of lead phosphato and acid phosphate.

It is impossible to have haemolytic changes on a large scale occurring in the blood without the formation of pigment and the storing up of iron in the liver, kidneys, and bone marrow, also of the cells of such of the internal organs as the liver and kidneys and the muscular fibres of the heart undergoing fatty degeneration. In addition, as the affected organs and tissues become hyperaemic, and structural changes occur in the capillaries, minute haemorrhages become possible. The bone marrow may recover fairly rapidly, so that newly formed blood corpuscles, such as normoblasts, and basophilic and polychromatic red cells, are found, which are regarded by some pathologists as signs of regeneration. Normoblasts may temporarily come under this designation, but I do not see how basophilic red corpuscles comply with the statement. The value of the research rests in the fact that early on in metallic poisoning the blood with its corpuscles is readily attacked, and with it the bone marrow. The reticulo-endothelial system also becomes involved, for Biondi showed that, after adding lead to the artificial culture of tissues, the connective tissue increased. Schmidt, Schrotter, and other writers draw attention to the early presence of polychromatic and basophilic corpuscles in plumbism. In a young female patient whom I saw treated by colloidal lead for intraperitoneal cancer, secondary to malignant disease of the ovaries, baso-

philia of a scanty nature developed, one or two corpuscles being observable in a field, and that usually not until fourteen days after an injection of colloidal lead. Blair Bell, who introduced this line of treatment, states that basophilia in these cases develops straight away, but such is not my experience, for occasionally basophilia did not appear at all after an injection, nor did nucleated red corpuscles. It is scarcely fair, however, to draw conclusions regarding the occurrence of basophilia in those cases where cancer is present at the same time, and whose toxins exercise a harmful influence upon the blood-making organs. It is only natural to expect that lead circulating in the blood in a colloidal state would adversely influence the erythrocytes, and that structural changes induced in them would be carried further by the cells of the reticulo-endothelial system. Schmidt offers an attractive explanation of the formation of the granules in polychromasia. With the breaking up of the nucleus of the cell, elements of the nuclear substance pass out of the membrane, and, mingling with the contents of the cell, the coarse granules become the basophilic particles. His opinion, therefore, is that lead acts primarily upon the haemopoietic cells of the bone marrow. Upon this and kindred points, however, the last word has not yet been spoken.

THE EARLY RECOGNITION AND TREATMENT OF CANCER OF THE STOMACH*

BY

EDMUND SPRIGGS, M.D., F.R.C.P.,
RUTHIN CASTLE.

In former days it was difficult to make an early diagnosis of cancer of the stomach because there was no means of recognizing the presence of organic disease until nutrition was impaired or a tumour could be felt.

Nowadays, by x-rays and chemical tests, the presence and nature of the lesion can be recognized at an early stage. But the prevalence of these and other scientific aids brings a new danger—namely, the danger of giving less time and attention to clinical inquiry. For if cancer of the stomach is to be diagnosed soon enough to give a reasonable chance of removing it, the first suspicion must arise from a study of the earliest symptoms.

In every series of cases the observer is struck by the length of time that has been allowed to pass between the beginning of the complaint and an adequate examination of the stomach. In my own series¹ the average time lost was about a year, the longest interval being two years. Thaysen² mentioned that, in hospital, cases have usually been treated six months or more. Eusterman³ reports that in 32 per cent of the inoperable cases at the Mayo Clinic the symptoms had extended over sixteen months.

We may ask how it is that in patient after patient symptoms of indigestion have been overlooked, or treated with a bottle of medicine or some alteration of diet for months or years. The answer is, of course, that there are a large number of people who have indigestion which is not due to cancer, and who do not develop that disease. Many of these treat themselves, but in many others the doctor is tempted or persuaded to treat the case for some months without having made a diagnosis. Indigestion is not a diagnosis, it includes several diseases, some almost harmless, others lethal. It may be due to errors of eating, drinking, smoking, to bad teeth, or to overwork and other strains with resulting functional dyspepsia. The symptoms of these conditions differ, as a rule, from those of cancer, in that, though often more severe, they are not so persistent, but pass off with appropriate treatment. Further, apart from the above causes, cases of chronic indigestion from organic disease, such as gastric or duodenal ulcer, appendicitis, or disease of the gall-bladder, may go on intermittently over long periods of time.

Experience does not enable the doctor to foresee the probable onset, and, excepting those cases with antecedent ulcers, the study of conditions predisposing to

* Health Series of papers published by the International Labour Office Geneva 1928.

* A contribution (abbreviated) to the discussion on July 20th at the International Congress on Cancer.

cancer of the stomach is so far barren as regards clinical value. Symptoms are not, as a rule, complained of before the growth is already there. Neither has the so-called biological diagnosis a practical outcome as yet.

EARLY SYMPTOMS

The early symptoms are generally regarded as vague and indeterminate, but they give, nevertheless, an impression of their own which should arouse suspicion earlier than it does—the impression of a disturbance of digestive health which, though not severe, does not pass away.

In making an analysis of symptoms in a series, patients seen casually or merely in consultation were excluded, 38 consecutive cases were taken, in all of which the clinical study was able to be combined with radiological, chemical, and, in some, operative examinations. There were 27 men, of an average age of 63, and 11 women, of an average age of 55.

The symptoms complained of in order of frequency were discomfort or pain in abdomen, lack of appetite, dislike of food, nausea, loss of weight, vomiting, flatulence or distension, heartburn and eructation, weakness, dysphagia or inability to take solids, constipation, haematemesis, diarrhoea, tumour.

It will be seen that the more frequent symptoms are those usually described—namely, pain, lack of appetite, vomiting, and loss of weight. These, with tumour, are the cardinal symptoms of cancer of the stomach, but they do not help us to make a diagnosis soon enough. Indeed, it is clear from the pathology that wasting and tumour are late results, and, from a clinical knowledge, that pain is so variable that no sound conclusion can be drawn from its absence. But to aid in making an early diagnosis we want to know much more than a numerical summary gives us. We want detail about the forms and variations of the individual symptoms, and about the order in which they are likely to appear, so that the earliest sign may draw attention.

When we put the symptoms in these patients, not in the order of frequency, but in the average order in which they first appeared, the following list was obtained: (1) discomfort or pain in abdomen not related to food, (2) loss of appetite or dislike of food, and nausea, (3) pain or discomfort after food, (4) heartburn and eructation, (5) flatulence, (6) vomiting, (7) regurgitation of mucus, (8) weakness and constipation, (9) loss of weight, (10) dysphagia or inability to take solids, (11) tumour. In three cases haematemesis was the first indication of the disease, and in two diarrhoea. The association of the symptoms with growths of different parts of the stomach has been described more fully elsewhere.¹

LABORATORY TESTS

No boundary should be recognized between the use of the hand, the stethoscope, and the test tube, or between the unaided eye and the extra and more penetrating means of vision that we have in x rays. Indeed when we see the arrest of a wave in the stomach we are observing a clinical sign just as truly as when a tumour is palpated at the bedside, and with much more chance of helping the patient.

Occult blood, as detected by the benzidine test, was absent in five cases, two of the cardiac end, two of the body, and one of the pylorus. Carson says blood is present in 75 per cent of these cases. Repeated examinations are desirable and the more frequently the test is made the more likely are positive results to increase. Occult blood is evidence of ulceration, or at the least of a lesion of a blood vessel over the tumour, and would not be expected to occur at the earliest stage.

A disadvantage of the usual benzidine test is that it is over-sensitive for clinical use, giving a positive reaction with traces of blood which are too small to be significant.

Since July 1927 my colleague A. J. Leigh has used Gregersen's modification of the test as described by Ogilvie,⁴ the technique being as follows: 45 mg of a mixture of benzidine 1 part and barium peroxide 8 parts (which mixture keeps well in a tightly stoppered bottle) are placed in a tube and 1 c.c. 50 per cent nitric acid added, making a 0.5 per cent solution of benzidine. (By using a marked tube weighings are avoided.) A fragment of faeces and a few drops of the solution freshly prepared are stirred on a glass slide. It is claimed that occult blood is present irrespective of diet if a definite blue colour appears within thirty seconds.

This method has proved of more value to us than the former one in which a boiled faecal emulsion and a saturated solution of benzidine in acetic acid were used. Thus of 200 different samples of faeces tested by both methods 43 per cent gave positive, 27 per cent negative, and 30 per cent doubtful results with the older method, whereas with Gregersen's technique 15 per cent only gave positive and the rest (85 per cent) negative results.

Achlorhydria is strong presumption of growth if any mechanical deformity is present. In this series test meals were given as a rule only in cases of doubt. Of 17 such meals, in 7 there was no free HCl, and in 6 others a trace only—that is, in 13 out of the 17 there was complete, or almost complete, achlorhydria.

It should be noted that cases with free HCl are often those in which the growth is removable.

X-RAY TESTS

As regards the detection of small tumours there are two schools of radiology—one which advocates the strine meal with screening chiefly, and the other the full barium meal. Any exclusive technique is to be avoided, and my colleague Mr O. A. Marver finds both methods valuable, but only with the full barium meal can the earliest evidence of gross lesion be obtained. It also shows, in favourable positions, what is the full extent of relaxation of the stomach.

Three radiological signs of a growth are: (1) an alteration of the strine picture, (2) a filling defect, showing that a solid lump is projecting into the lumen of the viscous—such defects are at first concave recessions in the shadows, known as finger-prints, (3) a very early sign is a local arrest of the normal peristaltic wave in a relaxed stomach wall. This sign is, of course, also found in ulcer, scarring, or fixation from firm adhesion. It is likely that the sign in cases of cancer precedes as a rule any clinical symptom. This arrest of a wave is not shown on an ordinary photograph; it can often be seen on the screen by a skilled observer, but the only way in which it can be demonstrated to others is by a series of films taken at short intervals, as with a slow cinematograph camera. Such an instrument has been devised by Mr Marver. The tracings from successive films when superimposed coincide at the area of growth, which is immobile, and there is usually but little movement for some distance above. This suggests that induration extends up a good deal, and shows during life what is found post mortem—namely, that infiltration of the submucosa on the cardiac side of a malignant growth is usually in advance of the apparent growing edge. There is not always enough peristalsis to give such definite tracings, but there is always more movement in the healthy part of the wall than appears to the naked eye. The statement of McVicar and Daly⁵ that there is an overwhelmingly greater chance of making a diagnosis by x rays than by any other method is in accordance with my experience.

Out of about 3,400 x-ray examinations of the stomach, of eight cases in which Mr Marver and I have been in doubt, one case has been lost sight of, two were growth, one was probably a tuberculous stomach, and four patients became well. If the radiological appearances are uncertain a second examination should be made after a month's interval. In some cases an arrest of peristalsis or a small deformity may cause grave suspicion. In such, if confirmed, it is best and safest to explore. The risk is small, 3 per cent or less, whereas the mortality of an untreated growth is 100 per cent.

DISCUSSION

It is clear on examining the analysis that there is no symptom that is always present and none that may not be absent. The same may be said of the signs with the exception of one—arrest of peristalsis at the site of the lesion, as shown by x rays.

The series confirms the main conclusion reached by students of this disease. Cancer of the stomach must always be kept in mind if a mild indigestion arises for the first time in middle age, and especially in a male over the age of 50. We may include here cases also in which, although there may have been indigestion years before, there has been a definite and considerable interval of freedom. Taking the two classes together, there were 29 out of 38 in whom a new indigestion had arisen within two years. But whilst absence of symptoms before the

illness is significant—being recorded in most of the patients—no reliance can be put upon a previous history of indigestion as excluding the probability of cancer in an elderly person. The chronic dyspepsia may become the subject of growth. Further, in every doubtful and unexplained case of loss of appetite or failing strength, early and rapid steps should be taken to exclude cancer of the stomach without waiting for anaemia and cachexia.

On reading and re-reading the histories, the conviction arises that in most of the patients more clinical care could lead to earlier diagnosis, and that a larger number of these patients with growths of the body or pylorus might have been treated surgically with success. The onset is generally appreciable, though it may be noted by others rather than by the patient himself. The fact comes out, and has been already mentioned, that in this series nearly a year was lost on the average. Most of this wasted time could be saved.

If we look at the problem as a whole it is clear that the biggest part of it is outside our consulting rooms, our clinics, laboratories, and our operating theatres. The hiatus, the leak, the reason for the continued enormous mortality, is at an earlier stage. It is therefore more important at the present time to direct the attention of the profession and the public to that stage. For not only do we doctors need to be stimulated in this respect. Many patients in this series had wasted time in going from one remedy to another and had not given their family doctor a fair chance. The public should know that it is more important to find out the cause of a chronic dyspepsia than to relieve it. We may go further, and say that it is wrong to treat indigestion in a middle-aged person without taking steps to exclude cancer, it is wrong to put cancer out of mind as long as possible, it is wrong to "watch the case." A patient with malignant growth may gain weight under dietetic treatment, a sense of security then arises which is false, for all the while his chance of cure is slipping away. Who can number the lives lost through treating an indigestion of unascertained nature or waiting for typical symptoms?

We should try in every case to form a diagnosis on the clinical evidence, but should lose no time in applying all other means at our disposal, and especially radiology. Early cancer can be recognized in the clinic, and the disease can be extirpated in a large number of early cases. It is possible, and we all hope, that better methods of detection may come to our aid in the future. But it is certain that much more can be done with the methods we have.

CONCLUSIONS

The study of the early symptoms in a series of patients with cancer of the stomach shows that the onset of the disease was appreciable in most cases.

In two-thirds of the patients the symptoms dated back more than nine months, on the average an interval of a year or more having elapsed before a full investigation was made.

An analysis of the symptoms in order of frequency, and of the order in which they arose, shows that the most important early symptoms are fullness, discomfort or pain, not severe or continuous but recurring persistently, and arising in a middle-aged or elderly person. The next symptoms in order of frequency and importance are lack of appetite, dislike of food, or nausea, with resulting loss of weight. Haemorrhage may be a first symptom.

The pain or discomfort is often relieved by food in cancer of the pylorus and of the body of the stomach.

Of the cardinal symptoms of cancer, wasting and tumour are late results, and pain is so variable that no security can be assumed from its absence. Anaemia is usual, though, in exceptional cases, the blood may be normal up to a short time before death.

When cancer arises in the subject of ulcer or other forms of dyspepsia there is often a recognizable change in the symptoms.

The earliest objective sign of cancer is probably local arrest of the wave in the stomach as shown by x rays.

This is demonstrated by the superposition of serial films taken at such an angle that the lesion is in profile. The sign is common to cancer, ulcer, and fixation by adhesion. A filling defect, or much induration, as shown by bending over of the shadow at the edge of an ulcer, is, as a rule, significant of cancer. The tests for achylia and occult blood are of great value.

It is wrong to treat indigestion for any length of time in a middle-aged person without taking steps to exclude cancer, indigestion is not a diagnosis.

If there is clinical and radiological suspicion of cancer, the risk of operation to make sure is much smaller than the risk of watching the case.

The fight against cancer is a fight for early diagnosis. If the delay between the onset of symptoms and investigation could be avoided, life could be saved or prolonged in a good proportion of cases. Further progress depends at present upon the profession and the public becoming alive to the fact that earlier diagnosis can and should be made.

THE DERMATOLOGICAL INDICATIONS FOR SOUTTAR'S CAUTERY

BY

HENRY C SEMON, M.D., M.R.C.P.,

PHYSICIAN FOR DISEASES OF THE SKIN, ROYAL NORTHERN HOSPITAL

A TECHNICAL description of the apparatus and the principles which underlie the application of heat at an approximate temperature of 100°C were published by Mr H. S. Souttar in the *Lancet* of April 17th, 1927.

I have used the apparatus both in hospital and private work for over two years, and am convinced that in dermatology it is much to be preferred to diathermy, which I have entirely abandoned, for the following reasons. There is little to be feared from breakdowns, in my experience so frequent with the electrical instrument, which furthermore requires the assistance and control of an expert in the theatre. With the steam-heated cautery the penetration of heat is relatively slow (about one inch per minute), while that of the diathermy plant, which depends on the electrical resistance of tissues and the strength of current, is correspondingly variable, and almost impossible to estimate. The diathermy coagulum is tough and leathery in consistence, while the other, although firm, can easily be removed with a sharp spoon. This is a great advantage, for we are thereby enabled to determine when the unhealthy tissues have been destroyed and normal planes reached. In two cases of epithelioma—one on the cheek, in x-ray burn following the treatment of lupus, the other on the oral cavity—I was enabled to avoid the disaster of complete penetration through mucous membrane in the one, and cartilage in the other, by keeping my finger on the distal side of the tissues exposed, and withdrawing the applicator when I began to feel the heat. Such a procedure would, of course, have been quite impossible with diathermy, with which I was once unfortunate enough to produce a permanent hole in a man's ear. In this case the epithelioma recurred, and was finally cured with Souttar's cautery and the sharp spoon.

The source of heat is a solid fuel, meta, which is cheap, and much safer than methylated spirit. The apparatus is therefore portable and quite independent of a lighting circuit. It must never be forgotten, however, that where there is a naked flame there is always the risk of a fire or an explosion, and other precautions should therefore be avoided whenever possible.

I have found local anaesthesia ideal in most cases, but where this is impracticable chloroform or intratracheal

A paper read in the Section of Dermatology at the Annual Meeting of the British Medical Association Cardiff 1928.

ether is perfectly safe, provided the boiler is placed two or three feet from the operating and anaesthetic tables. The disaster that overtook a case of malignant disease in the mouth, in which ether was exploded by the spark from a diathermy apparatus, will be fresh in your minds.

The only trouble I have experienced was a temporary blocking of the jet inside the applicator by chalky deposits from the tap-water used in the boiler. This might have been avoided by the substitution of distilled water or by inserting a small length of wire through the steam channels before lighting the meta. I would emphasize this precaution for although the risk of an explosion is nullified by rubber connexions, which are immediately blown off when the pressure becomes excessive, this contingency is not appreciated by the anaesthetist or the onlookers. Care must be taken to see that the water does not boil away during use, and I would advocate the fitting of a water gauge when new models are designed. The constancy of the temperature—about 100° C—is well maintained, and there is never any charring, although the applicators are usually blackened by a very adherent crust of altered blood, which creates that impression and considerably reduces the heat conductivity. The efficiency of the apparatus in coagulating tissue and arresting haemorrhage is thereby reduced, and I have found it necessary to scrub off the crusts in a 1 in 40 carbolic solution from time to time during the operation. This crusting does not occur with diathermy, because the heat is actually generated in the tissues themselves, and is, in my opinion, the only advantage which that procedure can claim over Souttar's instrument, as applied to the skin.

The arrest of haemorrhage has already been mentioned, and although I must have opened into arteries the size of the facial on more than one occasion, there has never been any difficulty in controlling bleeding as long as the applicators are kept free from crusts. Secondary haemorrhage occurred very slightly in the case of the buccal epithelioma above mentioned after separation of the sloughs, but it must be discounted by the fact that the growth was not eradicated, and rapidly recurred *in situ*. It has since recurred again after radical surgical excision (July 9th, 1928).

One of the most striking features of the method is the complete absence in every case of consecutive pain. Not even when sloughs separated from a tongue which had been treated for leucoplakia and papillomata was it a disturbing factor, and the patient was on a liquid diet for a day or two only.

The outstanding indication for the treatment, in my experience is epithelioma of all types, wherever it is accessible and irrespective of its situation. I have notes of fourteen such cases in my hospital and private practice. They include localizations on the pinna, the nose, the cheeks, the orbital angles and upper lid, the frontal bone, and the elbow. The diagnosis was confirmed in every case by the excision, just prior to the operation, of a small fragment for the microscope.

In the majority of these cases the cartilage was involved, thus rendering the application of x rays or radium relatively futile. In all these cases it has been my practice to combine the coagulation with the vigorous use of the sharp spoon, and to still the oozing thus engendered with renewed applications of the cautery, until the depth and appearance of the tissue exposed made it reasonably certain that a healthy plane had been reached, and that a recurrence was most unlikely.

My conjectures in this particular have been fortunate, for in only one case—advanced squamous epithelioma of the buccal mucous membrane, with large secondary sub-maxillary glands (referred to me by a surgical colleague as inoperable)—has a recurrence been brought to my notice. Since the above was written there has been a second case of recurrence. The patient in this case—a woman of 62—had a large rodent ulcer of perforating type involving the right maxilla and orbital regions. The zygoma was found fractured at the operation. After rapid healing the scar broke down and a recurrence became evident, from the region of the zygoma.

The method has proved extremely useful for lupus

verrucosus. In three such cases on the hands I previously macerated the horny materials with strong salicylic plasters for a few days, for the applicators had no effect whatever until this had been done, so complete is the heat-resisting property of keratin, it was then found easy to coagulate it, and I was much interested to note how the heat blackens the tuberculous nodule—probably by reason of its relative vascularity—and thus makes it stand out conspicuously against the white background of the scar tissue in which it lies. With the additional aid of a sharp spoon I was enabled to eradicate the nodules with such success and ease that up to late (about eighteen months) the first case so treated has not relapsed.

As might be expected from the poor resistance of the infecting organisms to heat, soft chancre and chancroids are exceedingly amenable to treatment by this means. In our venereal disease department at the Royal Northern Hospital we have cut short the extension of ulceration in two such cases, using only a local anaesthetic. For such cases I believe the cautery will ultimately prove the method of choice, for the bacillus of Dugrey is notoriously susceptible to the effects of heat, which is a more local and a cleaner method of attack than the liquid caustics hitherto recommended.

Granuloma pyogenium is another condition which is easily dealt with. The characteristic tendency to haemorrhage is immediately checked. I have cured one case of the intractable papillomatous type of leucoplakia of the tongue, which had been unsuccessfully treated with salvarsan and bismuth etc. for a period of over five years. This case was published in the *Lancet* of October 8th, 1927. Another such case was improved, and in yet a third, in which the process had recurred time and again after operation on the mucous membrane of the vulva, eventually becoming carcinomatous, I was able to relieve the patient of most of her distressing symptoms.

In summarizing the type of case in which my experience has so far taught me to expect good results I would emphasize that the pathological tissue to be destroyed must be soft in character and free from a covering of horny or keratinized material. This excludes the common wart and verrucous tumours generally from the indications, unless previously macerated by plasters. The coagulability of the tissue is of prime importance, and for this reason it will be found exceedingly difficult to destroy fibromata and moles of a fibrous structure, which should be surgically excised.

In addition to the conditions I have already specified there are some which I have had no opportunity of submitting to the treatment, but which I believe would be amenable. These include the malignant pustule of anthrax, Delli's case, and any condition in which a destructive with a simultaneous sterilizing action is required.

The after-treatment of the coagulum is exceedingly simple. In all cases an endeavour should be made to keep the wound dry until the slough separates. For this purpose the bismuth-formic-iodide powder (Mulford) and a sterile gauze dressing will be found useful, and when the second stage is reached and the raw surface is exposed I prefer ambrue to the use of boric or other ointments. If granulations are slow in appearing or of poor quality an occasional application of red lotion or pellidol (scarlet red) ointment is usually sufficient. On the whole there is very little trouble from complications, and so far I have met with only one case in which there was a tendency to a keloidal scar.

Conclusions

The steam heated cautery, especially when it is combined with the judicious use of the sharp spoon, is a most valuable destructive agent in dermatology. It introduces the new principle of coagulation at a constant temperature under conditions which are easily controlled. By its use the risks of haemorrhage and sepsis are greatly reduced, and the important factor of post-operative pain is entirely eliminated. These advantages, and the relative simplicity of construction and manipulation, render it the instrument of choice in the eradication of all malignant neoplasms and in many of the more intractable types of cutaneous granulomata.

THE THERAPEUTIC VALUE OF VALERIAN *

BY

J S MANSON, M D, D P H

THE newer claims of the various forms of psychotherapy for the treatment of the neuroses are likely to cause the older methods to fall into disuse, even into contempt. Like Macbeth, the psychotherapist would "throw physic to the dogs," and it is with the view of saying something in favour of valerian therapy—perhaps the oldest of all the methods of treating the neuroses—that I venture to contribute this short paper.

In 1904 when a student in the materia medica class at Edinburgh University I remember that Sir Thomas Fraser stated that the therapeutic value of valerian lay chiefly in its smell, and that any other effect was due to its carminative action. On starting in general practice, in which I did my own dispensing, I used valerian very sparingly at first because its valuable characteristic (smell) might have repelled patients rather than attracted them. When I did use the drug it was only in those cases where there seemed to be some functional disturbance for which no other drug was indicated. In such cases valerian was given to reinforce suggestion treatment through the olfactory sense.

In spite of a few mistakes in administering the drug I was greatly impressed with the success of valerian therapy in a large number of cases of the minor neuroses. The drug was given in the form of the ammoniated tincture of valerian combined with 10-grain doses of potassium bromide. I soon found that the bromide, while adjuvant, was not the essential part of the therapeutic value of the mixture, for if the bromide was given without the valerian the result was less successful or was even a failure. I attributed the action of the valerian to its effect in reinforcing optimistic suggestion through the sense of smell—a psychic rather than a physical or chemical action. Dr Dan McKenzie, in his book on "aromatics," shows how important is the sense of smell in awakening dormant memories of past experience, and Mr John H. Kenneth of Edinburgh University had an interesting note in the *British Medical Journal* June 3rd, 1922 (p. 804), on "osmics and psychoanalysis." Mr Kenneth thought that osmics—the science of smell—might be of use in psychotherapeutic practice. He wrote:

'In the course of experiments on olfactory fatigue and on associations and effects evoked by different smells, the remarkable visual and (to a lesser degree) auditory recollections of scenes and events, in some cases of more than twenty years ago hitherto forming part of unconscious memory, were extremely vivid as expected. The same olfactory stimulus may, of course release varied associations or groups of associations in minute detail. An emotional disturbance may be produced and in the presence of a complex a marked resistance is noticeable the smell stimulus being quite as potent as a word stimulus. Of the odorous substances experimented with musk otto of roses, tonka bean (cumarin) and cedar wood oil gave the most vivid results while resistances were encountered in certain cases with musk clove oil, and asafoetida.'

These observations of Mr Kenneth rather confirmed me in the view that the action of valerian was chiefly psychic. It produced an olfactory stimulus, which in time caused a break-up—if I may use the term—of complexes associated with fear and anxiety of external circumstances, or of apprehension of the functional working of the organs of the body—in other words, hypochondriasis.

Further experience in the use of valerian, especially the constant good results obtained when given in the type of case for which it seemed indicated, made me think that valerian had a more definite action due to some chemical factor rather than to an indirect psychical stimulus.

Let me give in general terms the type of case in which I think valerian is indicated. The symptoms usually described are palpitation, something rising in the throat, flatulent eructations, rumbling of the bowels, sense of pressure on the vertex, desire to be alone, and lack of interest in home and social surroundings, fear of something going to happen, restless sleep accompanied by disturbing dreams, lack of mental concentration, and general depression, so marked at times that thoughts of suicide creep into the mind—in other words, the first stage of melancholia.

Women are more affected than men, but I will give an illustrative case which occurred recently in my own practice.

The patient a man aged 54 was organically sound he was a confidential clerk in an important firm of solicitors dealing with the administration of large estates. He had nearly all the symptoms described above, and became totally unfit for his work. His firm, appreciative of the value of his services, sent him to a leading consultant who after a thorough overhaul advised a two months' holiday at the seaside, and prescribed glycerophosphates and other so-called nerve tonics to be taken regularly. On his return from his holiday by the seaside he found himself as bad as ever and could not concentrate on his work.

When he came to see me he described the misery of the seaside holiday. Each vacant day was succeeded by another one allowing him time to brood over his troubles. I advised him to continue at work, but only to do such work as to maintain his interest, and to avoid the mental fatigue involved in calculations. I gave him the ammoniated tincture of valerian in half-dram doses and 7½ grains of potassium bromide. In three weeks his confidence had returned and after six weeks he could undertake full work involving intense mental concentration in complicated problems of finance. During that period he had taken 12 oz. of the ammoniated tincture of valerian. He has had one or two tendencies to relapse since, but he returns for his smelly mixture to keep him up to the mark.

Similar cases could be cited, but they would be wearisome, suffice it to say that I am convinced that there is enough evidence to show that valerian does contain some definite property which has a decided and specific beneficial action on the higher levels—and perhaps also on the lower—of the central nervous system.

Continental pharmacologists have given more attention to valerian than their British colleagues, but even on the Continent research has been very limited, and the literature, such as it is, is not of recent date. The best account I have been able to find is an article in the *Pharmaceutical Journal* of November 19th, 1921 (p. 402), by Dr N. Smolaka of the Ministry of Health, Belgrade, entitled "The history and therapeutic properties of valerian." In this article Dr Smolaka described three experiments on frogs carried out by Professor Wicki at the Pharmacological Institute at Geneva. The frogs were immersed in 1 per cent, 2 per cent, and 3 per cent solutions of the liquid extract of valerian, and observations made of their behaviour. Dr Smolaka concludes that his experiments prove that the extract prepared and made by him was of high physiological activity and paralysed the brain of the frog in small concentration. He described the drug as an antispasmodic, because it depressed psychical action.

These experiments on the frog do not help us very much to understand the action of valerian on the human subject, all they do is to show that valerian has a definite action on the nervous system of the frog due to some chemical factor in the drug. It is stated by Cushny that valerian contains borneol, or Borneo camphor, and numerous esters of acetic, formic, and valeric acids. Is it possible that this borneol is the important active principle in valerian?

The action of camphor in depressing the brain and spinal cord is well known, but whether the allied borneol is the valuable active agent is a question to be determined by pharmacologists. All I have tried to show is that valerian is a very valuable drug in general practice, capable of restoring mental efficiency and alleviating mental misery. It has also the advantage of having no deleterious properties such as are associated with the habit-forming narcotic series of drugs. It seems to be a drug well worthy of further research into its properties and action on the nervous system.

A CASE OF FRACTURE-DISLOCATION OF THE ODONTOID PROCESS

BY

H C WARDLEWORTH NUTTALL, F.R.C.S.,
HONORARY ASSISTANT SURGEON LIVERPOOL ROYAL INFIRMARY

THE increasing number of motor accidents, many occurring in country districts, creates a corresponding demand for a fuller knowledge of injuries, especially of bones and joints, from all practitioners.

Fractures or fracture-dislocations of the neck are more frequently seen nowadays, even allowing for more accurate diagnosis. On general grounds I fear they may be expected to occur more frequently in the future, and I submit the following record as an illustrative case.

On June 20th 1928 the patient, a middle-aged woman, was sitting on the off side in the rear seat of a touring car. As the result of a collision at a cross-roads the car was turned over on to its rear side and the patient was thrown out the left side of her head striking a wall which bordered the foot path. Her husband after extricating himself from the driving seat found his wife lying in a huddled up position. She did not lose consciousness and complained immediately of pain in her neck. With the help of two other men she was carried into a neighbouring cottage her husband lifting her head and shoulders. He says that her coat was rucked up about the neck and thinks that it prevented any further displacement of the head.

Dr L. Hutchinson of Huyton who attended almost at once diagnosed a fracture of the neck fixed it temporarily and sent her to the Royal Infirmary by ambulance.

On admission she was suffering from shock. There was a scalp wound in the left fronto-parietal region but no signs of fracture of the skull. She complained of pain in the neck and on examina-

tion marked prominence of the upper cervical vertebrae could be felt with a depression above them. The head and neck were held rigidly on the trunk and the neck appeared unusually short, probably the effect of the contracted innates. Signs of injury to the spinal cord or cervical nerves were absent.

A temporary splint was applied, she was radiographed and treated for shock. The radiogram (Fig. 1) showed fracture of the odontoid process with considerable displacement forwards of the atlas and odontoid fragment.

The next day the arm and leg reflexes were increased and she had some retention of urine otherwise there was nothing to report. The following day the reflexes were normal and I reduced the dislocation under anaesthesia. Two assistants maintained steady traction on the head and neck by means of two traction loops, one beneath the chin and one behind and beneath the external occipital protuberance crossing one another at the vertex of the skull. I then grasped the neck firmly from the front with my fingers on the vertebrae posteriorly and my thumbs and index fingers along either side of the mandible. With a steady pressure of the vertebrae forwards and a tilting of the head backwards I reduced the dislocation with a slight but quite definite click. While the extension was maintained a plaster of Paris bandage was applied to immobilize the head and neck. Except for a mild cystitis and a little respiratory discomfort on one occasion due to the bandage her convalescence was tranquil and she was discharged from the hospital on June 30th under the care of Dr. Halton.

FIG. 1.

FIG. 2.

wire collar support fitted. A radiogram taken the next day is shown in Fig. 2, it reveals slight over-reduction if anything but this may be due partly to the position of extension of the cervical vertebrae in this radiogram as compared with the first.

Since September 1st the collar has been left off gradually and the range of movement has steadily increased. At the present time (September 22nd) nodding movements are free but tilting of the head from side to side is limited to 50 per cent of the full range.

I am indebted to Dr. R. E. Roberts for the first radiogram, and to Dr. J. H. Mather for the second.

TREATMENT OF NON SPECIFIC DIARRHOEA IN THE TROPICS

BY

C. V. THORNTON, M.B., Ch.B.,

BOMBAY

THE common occurrence of diarrhoea in children and adults in the tropics without any traceable cause is one of the main thorns in the flesh of the general practitioner. Very often his reputation will be made or marred by his success or failure to treat what is to the public a simple disease, but which in reality is a most complex condition.

In consequence of the innate conservatism of the profession the same old mixtures are copied religiously from textbook to textbook. Every mail brings pamphlets of new and futile proprietary drugs, drugs which are only equalled in their general inefficacy by their numbers. The four main types of tropical diarrhoeas are (1) the dysenteries, (2) sprue, (3) tuberculous or syphilitic, (4) diarrhoea not caused by any of the above.

The patient's history will generally serve to allocate the diarrhoea to one of these groups. Thus, in the case of dysentery there will be a history of pain and tenesmus; fever is a common accompaniment, and, of course, blood and mucus will be present in the stools. Here let me strike

a note of warning—never be satisfied with the patient's assertion that he has looked for these two phenomena—make sure for yourself.

Sprue is generally easy to diagnose. The patient seldom comes in the very early stages of the disease, and by the time the doctor sees him there are the typical signs of emaciation, putty-colored stools, and most probably the tell-tale sores in the mouth. Moreover, if you inquire closely, you will elicit a story of long-continued "indigestion" and flatulence.

Tuberculous and syphilitic diarrhoea are more difficult to diagnose. The former frequently shows signs elsewhere, or there is a history of an old pleurisy or some other lung complaint. The physical findings in the abdomen often help. As regards syphilis, if the possibility of this disease in all obscure cases of diarrhoea is borne in mind, and a careful history taken together with a blood examination, a mistake ought not to be made.

It is the fourth group that we are specially concerned with, and here the history of the case is nearly always the same. There is no pain, no change in the colour of the stools, which are liquid but otherwise normal in appearance. The striking fact is that ingestion of food causes an immediate evacuation, or, as the patients express it, "the food runs through them." Examination of the stools reveals nothing of note. The presence of undigested food,

and possibly an increase in the number of streptococci, will be the pathologist's report, from which the doctor may gather what comfort he may.

The duration has generally been about a week, this being the period adopted by most patients as being suitable for playing with advertised cures and sampling such old mixtures as their friends have been able to take up from their medicine cupboards.

The recent work of Scott and others tends to show that true spina is a deficiency disease in that the calcium content of the blood is below the normal, and also that some substance produced by the liver and as yet unidentified is diminished in quantity. This substance, which is probably of the nature of a hormone, is apparently responsible for the proper functioning of the intestines, and regulates the output of their digestive juices, and also the rhythm of their muscular contractions. Any interference with the production of this hormone results in the immediate non-digestion of food and the undue hurrying through of the bowel contents. Whether or not this is the case is only surmise, but all the latest work on the subject goes to prove the truth of this theory.

The treatment, then, of these cases of diarrhoea would appear simple, and so it is. First and foremost, purgatives have no place in the schedule at all. The patient must be put to bed for at least three days, preferably longer. All solid food must be stopped and only citrated milk or milk that has been peptonized given. Further, the milk must not be given in a large quantity at any one feed. A cupful of it should be administered every two hours. Bailey-water is allowed without restriction.

The mainstay, however, of the treatment is extract of liver, and this can conveniently be given as soup or in the powder form. In case this latter cannot be procured a short recipe for making the soup may not be out of place.

Take half a sheep's liver and mince it finely. Add four breakfastcupfuls of cold water and such spices as the patient may like. Boil down to two cupfuls, strain, allowing small particles of liver substance to come through, and give one cup in the morning and one in the evening.

In furtherance of the calcium deficiency theory, 15 grains of calcium lactate may be given thrice daily. The success of this treatment in these cases of non-specific diarrhoea is most striking, and any case which does not respond favourably in a few days should be regarded from a serious standpoint.

I have not mentioned two other common causes of acute diarrhoea in the tropics—namely, cholera and food poisoning. These are too obvious in their symptoms to allow of any such protracted treatment, and do not therefore come within the scope of this article.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL

A FOREIGN BODY OF UNUSUAL CHARACTER IN THE LUNG

THE following case seems of sufficient interest to warrant publication.

On June 11th 1928 a little girl aged 8 years, was brought to Dr Loughlin of Woolston because for the past few weeks she had been making a peculiar 'rattling noise' in her chest. He found that she was in good general health, that there were no symptoms beyond a low pitched expiratory stridor and no signs beyond rhonchi at the left base of the lung. He suspected a foreign body in the lung but the child's mother could give no history pointing towards this. He treated the child as suffering from bronchitis.

On June 15th the child was seen again and seemed in good health with the stridor somewhat diminished. Again the question of foreign body was raised and this time the child's grandmother gave the following history. Seven weeks ago the child was playing with some beads and had one in her mouth when she sat down to her dinner. She choked over the first mouthful of food, and to her dinner. She choked over the first mouthful of food, and when asked what was wrong said 'Oh it is all right the bead has gone'. (The beads are about half an inch in diameter and belong to a game called Gloria mosaic.)

In view of this history Dr Loughlin sent the child to the Royal South Hants Hospital where she was referred to me and I saw her on June 18th. There was then no stridor, she looked well but she complained of pain in the left side of the chest and her temperature was 100° F.

She was sent to the x-ray department but neither by screen nor on a plate could a foreign body be seen. The plate showed

dullness at the left base. As a bead identical with the one alleged to have been inspired was sent with the child, we had this strapped to her chest wall, and it showed up perfectly on screening. The radiographer was now convinced that there was no bead in the lung and the mother tried to help us by saying that the child had coughed it up. I was mystified and sent the child to the medical ward under Dr Fisher for observation.

During the next week the child looked ill, her temperature fluctuated, rising to 102°, she suffered from cough and asthmatic attacks, and the left lung exhibited varying physical signs. No diagnosis could be made except that of foreign body in the lung but we were puzzled by the x-ray findings. She was x-rayed again when a plate typical of an obstructed lung was obtained. The left lung was entirely dark and the mediastinum was drawn towards the same side. There was still no sign of the cause of the trouble.

Next day bronchoscopy was performed. On reaching the bifurcation of the trachea nothing could be seen because of the quantity of mucus present. On aspirating some mucus came away and then the tube became blocked. On removing it slightly it cleared and more mucus came but again the tube was blocked. As the child looked rather blue I removed the bronchoscope, with the aspirating tube inside, bringing with it a putty-like mass. I passed the bronchoscope again, but could see nothing as the trachea was full of mucus. The child was sent back to bed. She was very much better the next day, and within a week was sent home perfectly well.

I had one of the beads examined, and found that it was simply a mass of dried clay which, when soaked in water, became soft and putty-like and did not show a shadow to x-rays.

This case is not published as a successful bronchoscopic effort, as I never saw the foreign body until it appeared in the child's mouth. Its interest lies in the difficulty in obtaining a history and in the peculiar character of the foreign body, which was opaque to x-rays until it was inspired into the lung, and then it became non-opaque.

One wonders how many cases such as this remain undiagnosed, because had it not been for Dr Loughlin's shrewd suspicion and persistency this case would almost certainly not have come in for treatment.

Southampton.

W STEWART

HAEMOPHILIA IN THE TROPICS

DR HUGH THURSFIELD, in the *Tenth Book of the Practice of Medicine*, edited by F. W. Price, states that haemophilia is a disease of the temperate zone, nearly all the reported cases being of English, American, or German origin. The occurrence of haemophilia in the southern Punjab is therefore, I think, of some interest, and the following clinical details may be worth recording.

In 1923, when I was a student, I saw two brothers who suffered from this disease, and on inquiry it was found that all the maternal uncles of the children had died of bleeding in their childhood. The mother of the children had no sister, and no further information regarding bleeders in the family could be traced. The cases were not seen again or heard of.

In April 1927 a child aged about 3 years was brought from a distance of about eleven miles bleeding from a contused wound in the head. The father of the child showed great anxiety about the wound, which was not at all large and I immediately dressed the wound from which an aseptic discharge was coming. On inquiry it was found that the wound was about four days old. An elder brother of the child had died from uncontrolled bleeding hence the anxiety of the father. The child's mother had one sister who had no issue and her brothers had died from bleeding.

Since blood oozed later from the dressing I opened the wound and redressed it with a piece of lint soaked in normal horse serum. On removing the dressings after twenty-four hours a large clot was found in the wound but no oozing. The wound was dressed again with normal horse serum and subsequently ordinary aseptic dressings were applied daily to the wound which healed without further bleeding. During the treatment of the wound I gave hypodermic injections of normal horse serum, beginning with 1 c.c.m. and increasing the dose by 1 c.c.m. each time. I gave six injections at intervals of six days. While the injections were being given the child became weak and anaemic.

Six months after the course of injections the child was again strong and healthy but some peculiar abscesses were said to have developed. These were not seen by any medical man but it was stated that about a dozen small hard tumours appeared successively deep on the side of the neck came to the surface, burst with a whitish discharge and healed without treatment.

I saw the child again in June, 1928. There was no mark left by the abscesses or cysts. The child was quite healthy and though it had been scratched badly by a monkey, the bleeding stopped as in a non-haemophilic child.

The disease is rare and I cannot gather many instances, but I think the child did benefit by a course of injections with normal horse serum.

ACUTE GASTRIC DILATATION AFTER DOUBLE EXTRAUTERINE PREGNANCY

CASES of tubal gestation occurring on one side and followed some time afterwards by gestation on the opposite side are by no means rare. Extrauterine gestation on both sides at the same time is much rarer, but several cases have been recorded recently. I think the following case is sufficiently interesting to justify publication.

A married woman aged 31 with no children and no history of miscarriages was taken suddenly ill with acute abdominal pain on the evening of December 15th 1926. She was admitted to the Mansfield and District General Hospital several hours afterwards under the care of Dr S Kingsley Poole who operated upon her the same night. There was about a pint of blood and blood clot in the peritoneal cavity and a ruptured right ovarian pregnancy of about two months duration was found and removed. It was after removal of the blood present that an unruptured left tubal gestation was found this was of about one month's duration. The left tube was therefore removed. Ether anaesthesia was administered by Dr Archibald Macmillan.

The patient made very satisfactory progress indeed until December 19th three days afterwards when she vomited several times. The following day at 2 p.m. she suddenly became very ill. I found her collapsed, cyanosed and with epigastric distension. She was vomiting large quantities of offensive brownish fluid and she complained of abdominal pain. It was thought that she was suffering from acute dilatation of the stomach so pituitrin 0.5 c.cm was given intramuscularly and a stomach tube was passed and the stomach washed out. Large quantities of gas escaped from the tube. In a few minutes her condition improved which confirmed the diagnosis. A similar but less severe attack occurred once on each of the two following days and the same treatment was given.

For several days afterwards she appeared quite well. However on December 29th she vomited several times and on January 2nd she was again taken very ill with abdominal pain epigastric distension collapse and vomiting. The stomach was washed out as before and pituitrin 0.5 c.cm given with the same successful result. After this she rapidly improved and was discharged from hospital on January 15th 1927. An x-ray examination following an opaque meal showed no evidence of pyloric obstruction.

The case is of special interest as regards the attacks of vomiting. On three of the occasions mentioned she was extremely ill, and it seemed that unless something were done at once she would certainly die. And yet, following the treatment adopted, she responded surprisingly well and has since made a good recovery.

I am indebted to Dr S Kingsley Poole assistant honorary surgeon to the Mansfield and District General Hospital for permission to publish this case.

NEVILLE J FAIRBAIRN F.R.C.S.D.,
Late Senior House-Surgeon Mansfield
and District General Hospital

Reports of Societies.

GENITO URINARY FISTULA IN THE FEMALE

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on October 19th, with Dr J S FAIRBAIRN, the president, in the chair, Dr DOUGAL BISSELL of New York read a paper on genito urinary fistula in the female.

Dr Bissell recounted the early life of J Marion Sims, enumerating the difficulties he overcame and described how later in conjunction with Emmet, at the Woman's Hospital in New York, he gradually built up his world-wide reputation. Dr Bissell reviewed the work of this hospital, and compared the number of cases of vesico-vaginal and urethrovaginal fistulae operated on by Emmet between 1856 and 1866—namely, 275—with the number of cases operated upon in the last ten years—namely 58. He concluded that this difference must be attributed to the improvement in obstetrical management. In spite of this improvement however he believed that cases were still bound to occur for many years to tax the ingenuity of the surgeon. In a review of various operative measures for genito-urinary fistula employed prior to the work of Sims Dr Bissell mentioned Hayward's procedure, commenced in 1839 that of Mettner in 1847, and, in Europe the work of Lallemand in France in 1825, and Gosset in London in 1834. He then dealt in detail with his own methods of operation for this condition, and reported seven cases selected because they were unusual in type and origin, and served to demonstrate the value of Sims's technique when complications

were present. He added that Sims's achievement was something more than a stepping-stone, and that, while other forms of treatment could be applied in special cases, that of Sims was universally employable. Dr Bissell hoped, therefore, that interest would be aroused again in it, and that it would be re-established in the armamentarium of the gynaecologist.

The President remarked that, though he believed that in Sims's day silver wire was the most suitable suture material, at present, with the advance of asepsis and antiseptics other suture material, such as catgut, was more applicable.

Carcinoma of the Vagina

Mr J B BRIGHT BANTISTER, in the absence of Mr A C PALMER showed a specimen of carcinoma of the vagina in a patient aged 24, who had been married just over two years, but had not been pregnant. She complained of dyspareunia, and a blood-stained discharge for two months. Although she had been under treatment for syphilis for six years she still had a positive Wassermann reaction. On examination an ulcer with a hard everted edge had been found on the posterior vaginal wall, the surface of this bled easily. The diagnosis lay between chronic septic ulceration, gumma, and primary carcinoma. Microscopical examination proved the last of these to be the correct diagnosis, and the ulcer was therefore excised. About a fortnight later both sets of inguinal glands were removed, but they showed no evidence of growth. Ten weeks later the patient was again examined, owing to there being severe social pain accompanying defaecation, and was found to have a large ulcer on the anterior rectal wall. In spite of radium treatment the growth continued to increase, and the patient died five and a half months after the first operation.

ENDOTRACHEAL ANAESTHESIA

At a meeting of the Anaesthetic Section of the Royal Society of Medicine held on November 2nd, a paper on endotracheal anaesthesia was read by Dr I W MAGILL.

After briefly referring to the history of the method, Dr Magill summarized its advantages. These he classified under six headings: (1) The anaesthetist had complete control over the patient's airway under most conditions. (2) The anaesthetist was able to keep himself and his apparatus clear of the field of operation, and consequently did not impede the surgeon or interfere with his aseptic technique. (3) The surgeon could be protected from the anaesthetic-laden expirations of the patient. (4) The patient was protected against the possible entry of blood into the trachea. (5) There was, or should be, no tax upon the respiratory mechanism of the patient. (6) The method was dosimetric. The two main disadvantages of the method, which arose chiefly in private practice, were the variety and bulk of the apparatus required, and the necessary delay incurred in setting up the apparatus prior to operation. It would seem at first that the method was indicated in all operations on the head and neck not involving the vocal cords, and in all operations in which control of the airway was difficult or in which the surgical manipulations might cause respiratory embarrassment. There were exceptions, however. Cases of cataract were best treated under local anaesthesia or under nitrous oxide and oxygen. Intubation should not be employed, as it might lead to coughing. In exophthalmic and toxic goitre a combination of local anaesthesia with nitrous oxide and oxygen ensured the best after-results to the patient. Operations on the thorax gave better results when nitrous oxide or ethylene and oxygen were administered by means of a face-piece, and apparatus was provided for positive ventilation. Again, many operations were so trivial that, even if they caused some inconvenience to the surgeon and anaesthetist by reason of their situation they could be satisfactorily dealt with by simple methods. As regards the technique of endotracheal anaesthesia atropine was given in all cases and morphine where indicated. In the nervous and in children, excellent results were obtained with paraldehyde given per rectum an hour before operation. Cocainization of the larynx and fauces with minimal doses of 20 per cent cocaine solution from a nebulizer gave many advantages, of which perhaps the greatest was that

the vocal cords were at rest and muscular relaxation could be obtained with comparatively light anaesthesia. Induction of anaesthesia followed the usual lines. Intubation could be effected through the mouth or nose, and the latter was often the easier method. Free egress for expiration had to be provided. A pharyngeal airway might be all that was required, but in some cases the double tube method might be necessary. The latter had several advantages, and one disadvantage—namely, that the return flow from the trachea was no longer available for driving blood from the larynx. This could be overcome by suitable packing off of the larynx. Free respiration could also be secured by the use of one large tube. Intubation through the mouth with an efficient speculum and the introduction of a rubber expiratory tube was a simple matter. Double-channel tubes as so far produced were unsatisfactory. Intubation through the nose could be performed with a special forceps used through a direct vision laryngoscope, or, blindly, with the aid of a curved stylet. A rubber expiratory tube could then be passed without a stylet, and if there were no nasal deformity it would also enter the trachea. Objection had been made to this method on the score of the possibility of carrying infected material into the lungs with the catheter, but micro-organisms present in the nose were already present in the trachea, and, moreover, the author had so far never come across a case in which this complication had arisen. Maintenance of anaesthesia was effected by connecting the catheter to an apparatus capable of delivering air or nitrous oxide and oxygen under sufficient pressure, with whatever regulated quantity of ether might be necessary. The heating of the anaesthetic, despite the opinion of some authorities, was advantageous, especially when nitrous oxide and oxygen were used to vaporize ether without rebreathing. At the present time a combination of nitrous oxide, oxygen, and ether best satisfied surgical requirements, and the smaller the quantity of ether used the better the condition of the patient.

There were certain disadvantages in the use of nitrous oxide-oxygen without ether, such as heavy preliminary medication, the narrow margin between anaesthesia and recovery, and the difficulty of obtaining sufficient muscular relaxation. Chloroform had its advantages in dealing with robust or alcoholic individuals of the labourer type. In abdominal operations sufficiently quiet respiration of natural amplitude could usually be secured by open methods, and it was unnecessary to use actual apnoea produced by endotracheal insufflation. Where difficulty arose in controlling the airway a wide rubber tube permitting of to-and-fro respiration gave better results when passed into the trachea than did a catheter. The routine use of endotracheal methods in hospital was a decided disadvantage to the teaching of students. If these were equipped with no knowledge other than the control of the patient with the help of elaborate apparatus, they would be at a loss when called upon to anaesthetize a patient with a piece of lint and a bottle of chloroform. The author then summarized his conclusions as follows:

- 1 With certain exceptions endotracheal anaesthesia is the best method for operations on the head and neck and for any other operation in which there may be a difficulty in controlling the patient's airway.

- 2 Expiration should be provided for in endotracheal anaesthesia, either by means of a second tube or by a tube of sufficiently large calibre to permit of to-and-fro respiration.

- 3 Cocainization of the upper air passages has decided advantages in endotracheal anaesthesia.

- 4 The practice of blind intubation through the nose renders the method possible in cases where it is impossible to use a speculum.

- 5 The insufflation method is not specially indicated in abdominal surgery.

- 6 The routine use of endotracheal anaesthesia in teaching hospitals for every class of case is detrimental to the production of sound anaesthetic knowledge in students who are likely to become general practitioners.

In the discussion which followed, Mr H E G BOYLE criticized the use of paraldehyde as a preliminary narcotic, on the score of its nauseous qualities. He thought cocaine useful. He also questioned the use of a wide tube through the nose on the score of possible damage to the nose and

vocal cords. He liked endotracheal anaesthesia for abdominal operations, but agreed that it was not a necessity. Dr F L SURWAY thought that two catheters were unnecessary in most cases. Dr LANGTON HEWEN did not agree with the warming of anaesthetic vapours, especially as they frequently caused the patient to sweat. He liked endotracheal anaesthesia for operations on the upper abdomen. Dr H P FAIRLIE inquired as to the complications which might follow endotracheal anaesthesia. He himself had tried this method in many cases, and had had in all four deaths after its use from pulmonary complications. Dr F T EVANS questioned the use of a second tube owing to the possibility of damage to the larynx. He also was against warming the vapour. He preferred to give young children warmed port by the mouth instead of paraldehyde per rectum. Dr C H M HUGHES thought the double-tube method excellent. It allowed of adequate plugging of the pharynx. He inquired whether a pressure-gauge was necessary when the double tube was used. Dr Z MENNELL said that endotracheal anaesthesia had found a place in surgery. It was, however, unnecessary in tonsil and adenoid operations, and in those on the upper abdomen. He thought the double catheter unnecessary, for an airway would give equally good results. He liked warm vapour. Dr L POWELL agreed with the last speaker, as well as with the reader of the paper, as to warmed vapour. Dr S COFFIN wondered why the catheter tended to enter the larynx rather than the oesophagus when the nasal route was employed. Dr ASHLEY DALY liked to use the endotracheal method in goitre cases other than exophthalmic ones. He found warmed ether less irritating than cold.

After Dr I W MACILL had replied seriatim to these criticisms and queries the meeting terminated.

TESTS AND CLASSIFICATIONS OF HEARING

A MEETING of the Section of Otology of the Royal Society of Medicine was held on November 2nd, when the new president, Mr SOMERVILLE HASTINGS, took the chair and delivered an address.

Mr Somerville Hastings said that if the progress of otology during the past twenty-five or thirty years were reviewed he did not think there would be complete satisfaction with the results achieved. The prevention of affections of the middle ear had certainly to some extent been attained, and there had been an improvement in the technique of treatment, also it was possible now to arrest the progress of deafness resulting from sepsis of the nose and throat. But it had to be admitted that a good deal of middle-ear deafness, by whatever name it was called, with which otologists had to deal was but little influenced by treatment, nor were otologists yet agreed as to its exact pathology, what was true of middle-ear deafness was even more true of deafness due to trouble in the internal ear. He could not help thinking that the comparative ignorance concerning both the pathology and treatment of so much deafness of the middle and also the internal ear was due in part to the methods of examination employed in the past. It would be admitted by everyone that the methods of estimating hearing capacity by the distance at which a whisper, a conversational voice, or a watch could be heard, although of value clinically, was quite useless for scientific purposes. There should at least be a relatively pure source of sound, such as was produced by a tuning-fork or wireless valve. What he wanted to know before he could form a correct mental picture of a given case of deafness was the percentage of normal hearing which remained for every pure note between the upper and lower limits of audition. Then, if the degrees of cochlear and cerebral function were also estimated in percentages, it should be possible to say to what extent the deafness was due to changes in the conducting apparatus and to what extent to changes in the perceptive. He was convinced that, from the point of view of scientific advance, arbitrary units of hearing must be given up, and an attempt must be made to discover what percentage of normal power of conduction and of normal power of perception was present for pure sounds. In considering the principles involved in the estimation of the perceptive function, Mr Hastings went on to say that it was evident to all that the ordinary

methods of estimating bone conduction by means of a vibrating tuning-fork placed on the mastoid contained very many fallacies, since the more complete the interference with conduction through changes in the external or middle ear the longer would the sound of the tuning-fork be heard. The oft-repeated statement that in otosclerosis bone conduction was increased was obviously a misstatement if it applied to absolute bone conduction, but if it related to the application of the tuning-fork to the mastoid with the meatus open then it was perfectly true that in otosclerosis bone conduction was increased, as also in every affection of the middle and external ear. Indeed, in the most advanced cases of otosclerosis that it was possible to conceive there could not be a greater increase of bone conduction than was present when the meatus was fully plugged by a large piece of wax. Turning to the assessment of the total hearing capacity, Mr Hastings illustrated the method which he himself favoured of estimating hearing by means of a tuning-fork at a fixed distance, and immediately comparing the time for which it was heard by the patient with the time for which it was heard by a normal person, usually the examiner himself. In conclusion, he said that the investigations regarding otosclerosis would never really prosper until there was standardization of the methods of testing hearing capacity, the time had come for the Section to make another attempt to solve this important problem.

Dr J KERN LOVE submitted an educational classification of deafness based on the effects of this infirmity on efficiency in early life. For educational purposes whispered speech heard at a distance of 20 ft was taken as normal. In the first class were deaf mutes, congenitally defective, in the second class came the muted or semi-muted, totally deaf because of disease (chiefly nerve deafness) occurring shortly after birth, the third class consisted of the speaking deaf, persons deaf from disease occurring after two years of age and the fourth class—by far the largest—contained the partially deaf or hard of hearing suffering chiefly from middle-ear disease. The first two classes of children had to go to special schools for deaf mutes, the third to special schools for the deaf, while for the fourth the educational provision might be a front seat, or a small class in a hearing school. Hearing tests, and also treatment, were useless in the first three classes; in the fourth class not only was hearing present, but it might be improved. With regard to the association of syphilis with congenital deafness the speaker gave some figures from Glasgow which showed that only 2.6 per cent of the congenitally deaf children had a positive Wassermann reaction. He urged intensive study of otosclerosis with a view to its prevention.

Dr T A CLARKE spoke of some work on hearing tests at the Lereux Institute of Otolaryngology at Middlesex Hospital, to which the remarks of the president had already furnished an introduction. He emphasized the necessity for a consideration of the hearing tests at present in use. In the testing of tonal limits the present tests were accepted as satisfactory, but he drew attention to the anomalous results of comparison of perception of the monochord by air and bone conduction, and criticized the Rinne, Schwabach, Gelle, and other tests. The "absolute bone conduction" test afforded an absolute index of the perceptive component of hearing (nerve function). For the quantitative determination of hearing power the results expressed on a distance basis, and in comparison with a normal, were to be preferred; these results were the simplest to obtain, and had the advantage of being intelligible to the untrained mind. For distance tests a watch was useful, but the instrument known as the electrical audiometer, while valuable for research, was, he considered, impossible for ordinary clinical use, owing to its complication and lack of portability. Tuning-forks yielded accurate results, and he described some of the mathematical considerations underlying their use. He showed tables indicating how in a routine method of testing with tuning-forks relative efficiencies were determined and expressed.

Mr O O PORRER said that the president and Dr Clarke had both spoken of a tuning-fork being held at a constant distance from the ear. He wondered how that distance was maintained in view of movements of the patient, also how the normal was constituted with which the patient's hearing was compared. The Gelle, Schwabach, and Rinne tests

were not actual hearing tests *per se*, they were designed to show that conduction was hyper- or hypo-functional. The disadvantage of the tuning-fork was that no two identical sets of tuning-forks could be devised, there was also the possibility of error in regard to supposedly constant distance and supposedly normal standard for comparison. He had found the audiometer portable and simple to use.

Sir J DUNDIE GRANT expressed himself as disturbed by the iconoclastic remarks of the two previous speakers. He thought that tests for hearing were apt to be taken too seriously, when they were reduced to figures and multiples, many almost innumerable factors connected with deafness were likely to be neglected. No doubt the too heavy tuning-fork would not give any very satisfactory results. A tuning-fork which sounded for about twice as long opposite the meatus as it did upon the mastoid would be about right.

Mr A R TWEEDIE criticized Dr Kerr Love's standard of whispered speech heard at 20 ft distance being taken as the normal. This was a purely arbitrary division between cases of children requiring special treatment and cases suitable for education in ordinary schools. Mr G J JENKINS pointed out the difficulty of placing tuning-forks in exactly the same position and at the right angle in each case, no matter how carefully the examiner might educate himself in their employment. Mr A J STONY (secretary, National Institute for the Deaf) said that the National College of Teachers wished to establish a properly classified system of education for the deaf in this country, at the moment there was practically no classification at all, and children with varying degrees of deafness were placed together in the same school, and often in the same class. Obviously this was unscientific and unsuited to the children's best interests. The College was desirous, as a preliminary piece of work, of devising a terminology of deafness based on history and degree such as would be intelligible to the ordinary teacher, and also to the general practitioner who might not know very much about deafness. Mr A D SMITH pointed out that there was another class in addition to those which Dr Kerr Love had described—a small class of hearing mutes, who understood what was said to them, but were unable to speak. He also said that in applying tuning-fork tests he had discovered in some cases a "blind spot" interval, the person would say that the vibrations had ceased, and then after two or three seconds discover that he heard them again.

Dr T A CLARKE, in reply, said that a little practice enabled one to maintain a fairly constant and accurate position for the fork. As for comparison with the normal, and the question of what was normal hearing, he was content to accept his own normality until he was proved abnormal.

FIBROSIS OF THE LUNG

At a meeting of the Section for the Study of Disease in Children of the Royal Society of Medicine on November 5th, with Dr F J Poynton in the chair, Dr L S T BURRELL opened a discussion on fibrosis of the lung.

Dr Burrell said that since many chronic pulmonary diseases started in childhood it was important to recognize and treat the various catarrhal conditions which occurred. Except as part of a general infection pulmonary tuberculosis was not common in infants. During the first few years of life the mortality was high, but thereafter it rapidly fell, so that between 7 and 16 there was a very small mortality from tuberculosis. After 16, however, the mortality rose to a maximum at about the age of 50; the figure varied in different countries. Tuberculosis of the glands at the root of the lung was frequently present in children, but it was most exceptional for the lung tissue to be subsequently infected. Dr Wingfield had examined 150 hardened specimens of the thoracic contents of children who had died from various diseases, and found naked-eye evidence of tuberculosis in the glands at the root of the lung in 17.5 per cent; this was confirmed afterwards by microscopical examination. In the early case and in the late stages where fibrosis existed there were frequently no tubercle bacilli in the sputum, unless the patient had a cold or a catarrhal attack. In the adult with signs at the lung apex a tuberculous origin was assumed, generally rightly; this was not so in early life, and in the child with an acute apical lesion the prognosis

was better than for a similar condition in the adult. In the majority of cases of children with apical or other lesions which cleared up, the disease was non-tuberculous. But tuberculosis played a great part in producing fibrosis, and the catarrhal conditions in childhood were very important from the point of view of the individual child and of other children associating with it, many of these cases went on to bronchiectasis. The chief cause of catarrh in children was measles, and next influenza and whooping-cough. In 1925 there were over 94,000 deaths in England and Wales of children under the age of 15, more than 20,000 were caused by non-tuberculous respiratory diseases, some 1,500 being due to pulmonary tuberculosis and 5,000 to other forms of tubercle. The importance of non-tuberculous respiratory diseases in children should be recognized. In lobar pneumonia the exudation became completely absorbed and the patient recovered in most cases, but in the broncho-pneumonia after influenza and measles there was destruction of the bronchial membrane and lung tissue, and the damage remained. Cases of unresolved pneumonia were of this nature, and therefore it was the broncho-pneumonia type of trouble which led on to the fibrotic cases. A child would return to hospital time after time, at intervals of a month or two, and always with the same part of the lung affected, which could not be a coincidence, meanwhile fibrosis was probably occurring and leading to bronchiectasis.

Dr MARLAND JONES agreed that tuberculosis was a somewhat rare cause of fibrosis of the lung in children, a condition sometimes discussed was epituberculosis.

Dr HILDA STÖESINGER had been following up consecutive cases of lobar pneumonia and broncho-pneumonia at the Royal Free Hospital to try to note the early stages of pulmonary catarrh and pulmonary fibrosis. She had repeatedly found cases with just a localized pulmonary catarrh occurring every two or three weeks, and many patients who had been diagnosed and treated as cases of lobar pneumonia showed catarrh. In both lobar pneumonia and broncho-pneumonia many patients had been in contact with respiratory disease, or had had recurrent attacks of bronchitis and pneumonia, but in many cases of repeated local catarrh and early fibrosis there was no x-ray evidence of disease. On the other hand, certain cases with generalized bronchitis and emphysema were found radiologically to have local fibrosis, though there were no clinical localizing signs. Syphilitic induration of the lung in young infants might, perhaps, cause some of the rarer types of pulmonary fibrosis. Dr C D S AGASSIZ said that tuberculosis of the pulmonary kind was not uncommon in children, judging by the appearance of tubercle bacilli in two sputum. In fibrosis of lung the signs were most marked at the base, sometimes at both bases, the condition cleared up quickly, and then the patient returned.

Dr H C A BOLDERO paid a tribute to the good done by child welfare agencies in catarrhal conditions in children, but thought little was done by them for gastro-intestinal states. He advocated preventive inoculation. Dr A G PHEAR agreed that lung fibrosis and bronchiectasis in children were fairly common, and, since they were relatively rare in adults, perhaps most of these patients died, but he had observed cases in which a child had such definite signs which, a few years later, had disappeared. Cases of slowly resolving pneumonia might be diagnosed as fibrosis and bronchiectasis, in other words, a changing condition might be regarded as a permanent one. Dr G A SUTHERLAND held that bronchiectasis was an exceptional termination of fibroid lung. Broncho-pneumonia could be clearly distinguished from lobar pneumonia, since the clinical course was so different, probably lobar pneumonia never led to fibroid lung. It was very necessary to distinguish pulmonary tuberculosis from chronic fibroid lung. A large number of patients with fibroid lung recovered. Dr PARKES WEBER doubted whether cases of slight recurrent attacks of pneumonia clinically led to fibrosis.

The PRESIDENT expressed surprise at the manner in which some of these patients recovered, even though the condition had been so severe as to cause displacement of the heart. He agreed that the infant welfare centres prevented many of the respiratory troubles. The surgical treatment of emphysema was an important question. He was not in favour of vaccines for these children.

INJECTION TREATMENT OF VARICOSE VEINS

A MEETING of the Brighton and Sussex Medico-Chirurgical Society was held on November 1st, with the President, Mr GEOFFREY BATE, in the chair. Mr ST GEORGE B DEFLEBLE GRAY read a paper entitled "The injection treatment of varicose veins: anatomical, physiological, and practical considerations," and Dr H M GALT showed three microscopical slides illustrating changes in the vessels.

Mr Gray first of all outlined the anatomy of the superficial veins of the lower limb, and stated that the anatomical factors making for varicosity were (1) height of column of blood—average length of great saphenous is 85 cm, (2) thinness of its walls and lack of muscular support, (3) possible variations in the anatomical course of the small saphenous and its anastomotic channels. He then gave a short historical summary. The first intravenous injections of drugs were made in the year 1657, at the suggestion of Sir Christopher Wren, but intravenous therapy was impracticable until the invention of the Pravaz syringe in 1851. Shortly after this date experiments were made with the injection of solutions of ferric chloride into varicose veins. There were many successes, but also many failures due to septic sequelae, embolism, etc. During subsequent years various solutions were used for injections. There were many successful cases, although some caused great pain to the patients, whilst other patients had trouble from sloughing, scarring, and recurrence. He found that sodium salicylate caused severe pain, though the results were excellent. He now used quinine and urethane, and always injected the patients standing up. After detailing his method of giving an injection, he said he did not see the reason for injecting slowly, as it must surely militate against the success of the injection if the fluid becomes diluted. In female patients it was important to exclude pregnancy as a cause or a concomitant of varicose veins, as the injection of quinine might possibly lead to abortion. The majority of solutions used in the injection treatment of varicose veins were self-stealing. He recalled that in the recent discussion at the Royal Society of Medicine only one speaker was definitely opposed to injection of varicose veins, on the ground that it led to pulmonary embolism, and the solution he used was concentrated glucose. Mr Gray very briefly referred to the treatment of haemorrhoids, for which he used a 20 per cent solution of carbolic acid, and suggested that similar fluids might be injected into subcutaneous naevi as into piles. He suggested that varicocele also might be amenable to treatment by injection. He concluded by giving his reasons for believing the risk of quinine blindness after injection of quinine to be negligible.

After the paper, which was illustrated by diagrams, Mr Gray showed a table designed by himself for the patient to stand on, and demonstrated two cases treated by him.

At a meeting of the Royal Society on November 8th Dr J A MUNRAI communicated a paper by Mr R J Ludford and Dr W Cramer on the mechanism of the secretion of the thyroid gland. The authors reported that the cells of the thyroid gland discharged their secretion into the lumen of the vesicle and thence into the blood stream. There was no alteration in the direction of the discharge during prolonged increased functional activity, there was also no evidence that the cells secreted normally direct into the capillaries. In exophthalmic goitre in both the mouse and man there was enlargement of mitochondria and of the Golgi apparatus—a condition characteristic of intense secretory activity, the polarity of the Golgi apparatus was frequently reversed. The secretion droplets, formed in association with such a reverse process, in the case of the mouse were discharged directly into the capillaries. Thyroid secretion in exophthalmic goitre differed therefore, from that in the normally active gland in respect of the direction in which the specific secretions discharged. Whereas normally the secretion passed first into the lumen of the vesicle, in exophthalmic goitre it entered the capillaries. The authors explained the pathological condition on the basis of this difference in the mechanism of the secretion.

Reviews.

RADIOLOGICAL DIAGNOSIS

UNDER the title of *Röntgenology The Borderlands of the Normal and Early Pathological in the Stigram*¹ we find a translation from the German by Dr ARTHUR TURNBULL of the well known and indeed celebrated work of ALBAN KOHLER of Wiesbaden, which has already run through several editions. This English translation is from the fifth and last edition. There can be no doubt that this book is a radiological classic, and the translator has rendered a great service to those interested in the subject who do not read German. Possibly it may be a too literal translation, and this occasionally renders passages somewhat obscure and difficult to understand, on the other hand, this method of translation is perhaps the best, inasmuch as it gives a better insight into the author's own ideas and practice.

There is no book on radiological diagnosis written on the same lines as Kohler's, and it has filled in gaps which exist in most of the other works. Practically all the illustrations are line drawings from the original radiographs, and as it often happens that very slight alterations from the normal are being discussed, these can be made clear on drawings where they would be lost in attempting to reproduce the radiographs themselves. That part which is given to bone conditions is a remarkable piece of work, full of detailed observations on mainly small things—many of them, however, of the greatest radiological importance—which have never been brought together before. The cross references are a great help, and Alban Kohler has left his own stamp on practically every page. It is interesting to note that apparently the author does not use the stereoscopic method for his examination of bone and joint conditions. Certainly he makes no reference to the great advantage of stereoscopic views of the shoulder-joint. A number of difficulties alluded to, which give rise to the remark that "the judging of shoulder radiographs is one of the most difficult tasks even for the skilled worker," entirely disappear when stereoscopic views are examined.

While considerably more than one-half of the book is given up to the consideration of bone conditions, there are separate sections on the lungs and pleurae, the diaphragm, the heart, the aortic arch and associated vessels, the oesophagus, the liver, the kidneys, and finally the stomach, duodenum, and bowel. There is a good index, and footnotes on almost every page serve as fingerposts to important literature. Many English references not present in the German edition have been added.

The translator is to be congratulated on his work, and the excellent manner in which the book is presented to English speaking readers should give pleasure to the author. Professor John Fraser, Dr J. M. W. Morison, and Professor James T. Case have written short prefaces, and we can unhesitatingly agree with Dr Morison when he writes that this book is a necessity for the student who is studying with a view to a diploma in radiology. We can go further than this, however. It is indispensable to all radiologists and orthopaedic surgeons, and many others should find it of great use.

ABNORMAL PSYCHOLOGY

PROFESSOR EDMUND CONKLIN regards the study of the psychology of the abnormal as indispensable to the practice of medicine, but his *Principles of Abnormal Psychology*² has been written for the student of psychology rather than for the medical practitioner. The author's point of view is strictly psychological throughout, and therefore no space is devoted to the consideration of the various therapeutic measures which are generally employed for the

alleviation of the disorders described. This work is none the less one which should attract many medical readers. It deals with psycho-pathological phenomena with which medical men have first-hand acquaintance, and it affords a comprehensive survey of the many problems which these phenomena present. The order of presentation of these phenomena differs considerably from that which is generally followed in the majority of textbooks. The author has preferred to place quite early in his work chapters dealing with the psychoses proper, so that the reader may later approach the study of borderland phenomena (hypnotism, suggestibility, spiritism, etc.) as so much clinical material to be studied in the light of the knowledge which he has previously gained of the psychoses. It is not clear what advantage is derived from this plan, as the outline of the psychoses given seems to afford scanty enough material for the elucidation of these other problems, but at any rate it is the method which Professor Conklin's teaching experience has convinced him to be the best.

The description of the various psychoses is necessarily brief, and might with advantage have included an account of the delirious states which are cursorily mentioned in the chapter on dreams. The problems underlying the production of illusions and hallucinations are discussed in the light of the rival "central" and "peripheral" theories of their origin. The psychological aspects of memory abnormalities are clearly portrayed. The author's presentation of psycho-analytic doctrine is singularly free from bias, and his attitude scientific and non-committal. The chapter on dreams is good, though the author's allusion to the evidence that dreams are to some extent dependent upon endocrine balance appears to be beside the mark in a psychological treatise. In the very excellent bibliographical references appended to this chapter, as to others, we should have liked to see mention made of Freud's *Introductory Lectures*, more serviceable perhaps in this respect than *The Interpretation of Dreams*.

Hysteria and the other psychoneuroses are skilfully presented. The commotional and emotional disturbances occurring in "shell shock" are fully described. In a brief chapter on multiple personality, Professor Coulin has managed to compress much information and to dispel many misconceptions. He makes essentially clear, what many writers fail to do, the distinction between a true condition of multiple personality and the many dissociated states which are often mistaken for it, and his reintegration of the views of Janet and of Freud is suggestive. Subjects discussed in other chapters are sleep and its abnormalities, the mental effect of drugs, feeble-mindedness and genius, and in a "biographical background" are briefly sketched the contributions of the leading workers in psycho-pathological problems, from Plato to Freud.

POSTURE

SIX authors have contributed to a small book on special gymnastics and other means of attaining bodily soundness.³ Among these is the well-known orthopaedic surgeon Professor FRITZ LANGE of Munich, who not only has edited it and written the introduction, but has also contributed the article on posture defects and bodily exercises.

Professor Eugen Matthias writes of the physiology of exercise and the pathology of faulty posture in a philosophical manner, stressing not only the effects of proper exercise on the bodily health but also on the mind, which is so inextricably connected with the nervous and muscular systems. Dr L. Gebhardt discusses camps of exercise for young persons and schoolchildren, such as one to which, in 1926, the Munich surgical clinic sent eighty pupils. Professor Trumpp has written the article on problems of nutrition, in which he discusses at some length questions of metabolism and diet in their relationship to health and disease. It is rather refreshing to find in such a scientifically written article "improvement of the constitution" set forth as a principal object. That shadowy entity had, we thought, long been relegated to the shades of popular hygiene.

¹ *Röntgenology The Borderlands of the Normal and Early Pathological in the Stigram*. By Alban Kohler. Translated by Dr Arthur Turnbull. B.Sc., M.D., Ch.B. Glas. London: Baillière Tindall and Cox, 1928. (10 x 7 pp. xviii + 656. 324 figures, 42s. net postage 9d.)

² *Principles of Abnormal Psychology*. By Edmund S. Conklin. Professor of Psychology, University of Oregon. London: G. Allen and Unwin Ltd., 1928. (Demy 8vo pp. vii + 457. 15s. net.)

³ *Das Menschenen Sonderheiten und andere Wege zur Körperlichen Erhaltung*. Herausgegeben von Dr. Fritz Lange. München: J. F. Lehmann, 1928. (6 1/2 x 9 pp. 106. 78 figures. 3M.4.0.)

In this country it would be difficult to write an article on faults of posture and bodily exercises without reference to the work of Goldthwait and his colleagues in the United States, where that distinguished orthopaedic surgeon has for so long advocated posture culture. In Germany Professor Lango achieves this feat with ease perhaps by ignoring the merits of Boston in this connexion he is trying to neutralize his error in 1926 when, as we noted in our review of his work on the treatment of fractures, he credited the Americans with the introduction of the Thomas splint in war surgery (*British Medical Journal*, March 6th, 1926, p. 428). But one error does not atone for another. Were it not for this, we should commend the essay, which is well illustrated. Professor Lange remarks, as English writers have done some time ago, on the exaggerated sacro-iliac angle shown in nude figures of the great age in Greece. An interesting observation of his is that in a blind asylum he was able to pick out those girls who had been blind from infancy by their deplorably bad posture. The cause which he assigns for this fault may or may not be the true one, and further investigation seems necessary.

The most practical article in the book is that by Dr Aubry on special gymnastics. This should be valuable to those in Germany who have to deal with this matter. It is freely illustrated. The last article is that on scoliosis and the forms of the thoracic cage, and contains as much on this difficult subject as can be compressed into less than eleven pages. Like most German medical works this handbook is well got up.

ELECTROCARDIOGRAPHY

WE have to announce the receipt of new editions of two books dealing with the subject of electrocardiography. That entitled *Clinical Electrocardiography* by Sir THOMAS LEWIS has now reached its fourth edition, and is so well known and so highly valued that it requires scarcely more than a notice of its appearance. There is little change from the previous edition, which appeared five years ago, with the exception of a few pages dealing with thrombosis of the coronary artery. The improvement in the paper is warranted by the greater clearness of the illustrations.

Dr HAROLD E. B. PARDEE's book on *Clinical Aspects of the Electrocardiogram*,⁵ now in its second edition, is more pictorial and covers ground not aimed at in the work just noted. The types of apparatus described make it perhaps more suited for the American reader. It contains numerous records and much valuable information.

LOW BLOOD PRESSURE

Dr HALLS DALLY has supplemented his book on *High Blood Pressure*, now in a second edition, by a companion work on *Low Blood Pressure Its Causes and Significance*⁶—a subject which, though without the same clinical appeal, deserves proper consideration and investigation as to its possible bearings in a wider direction than is to-day realized. It is therefore useful to have a full survey of the present position, such as Dr A. Friedlander's monograph on hypotension, which appeared last year. Dr Dally has gone over the literature thoroughly, and presents the opinions of other writers in a manner which will prove useful to the reader anxious to obtain this information. In addition he gives his own views, for example, that in individual with hypoplasia—a word which (dutifully following the late Sir Clifford Allbutt) he prefers to 'the truly dreadful hybrid hypotension'—is never normal, whether the condition of low arterial pressure be congenital or acquired, for in what is described as "the author's biological law of low arterial pressure" it is always to be regarded as an expression of low vitality. What level should be regarded as the limit of low blood pressure is discussed in the light of various

estimates, and the author finally concludes that the upper limit is 110 mm Hg for men and 105 mm Hg for women for the systolic pressure, and 66 and 62 mm Hg in the two sexes for the diastolic pressure. The occurrence of hypoplasia in various diseases is considered systematically, and thirty pages are devoted to the subject of treatment. Dr Dally takes an optimistic view about the influence of organotherapy, and his experience of ephedrine, the alkaloid of Ma Huang which has been extensively used in China for more than 5,000 years, is most favourable.

CIVILIAN EYE INJURIES

PROFESSOR SCHNEICHLER has written a monograph⁷ annotating his experience and observations on a large series of 2,300 eye injuries met with in civil life. The highest incidence occurred in the trades dealing with stone and building, although during the war years a greater increase of accidents in metal workers was apparent. It appears that his task has been rendered difficult by a lack of co-operation between the consultant and the medical attendant who first came into contact with the cases, but, even so, he has reached some interesting conclusions. His statistics show that the percentage of those claiming disability from injury who have previously incurred disease of the eye is high, and that stimulation of eye injuries is common. This may be so misleading to the ophthalmological examiner as to present a homonymous hemianopia. The assessment of disability should properly be determined by the ability to resume earning capacity, but in ocular injuries an unbiased judgement is difficult to form, because of the prevalence of a functional element persisting after the accident. To differentiate functional and organic consequences required much conscientious study. Intra-ocular tumours, irido-cyclitis, retinal detachment, pneumocystic keratitis, glaucoma, and cataract were frequently found in association with injury, but in 80 per cent of the cases a decision was come to that these were quite independent of the accident, while only in 20 per cent could any relationship—and that a very doubtful one—be conceded.

NOTES ON BOOKS

IN the third, and much enlarged, edition of their book entitled *Ultra Violet Radiation and Actinotherapy*⁸ Drs ELEANOR and W. KERR RUSSELL issue a timely warning against the wave of quackery in relation to actinotherapy that is sweeping the country. They emphasize the fact that it is almost as perilous for anyone to use ultra violet radiation without skilled knowledge and training as it is for a layman to prescribe and administer some virulent poison, or to endeavour to perform a surgical operation⁹, and they quote with approval the British Medical Association's Memorandum on Treatment by Radiation and Electricity, published in the *Supplement* to our issue of April 28th, 1928 (p. 149). On the other hand, when remarking that the setting up of special physical treatment institutions, where patients may be treated at a moderate charge by teams of qualified practitioners, is full of promise for the future, they might well have added a word about the risk of commercialization that attaches to such enterprises. The book on the whole is good and well written. It embodies the results of a great deal of personal experience and of wide reading.

We welcome the appearance of the first volume (Abdominal typhus Balneologie) of the new German dictionary of practical medicine,¹⁰ edited by Professors GEORG and FELIX KLEMPERER assisted by 120 collaborators whose names are well known to students of German medicine. The work embraces the whole field of medicine in the widest sense of the term, but, as the subtitle implies, it is mainly concerned with internal medicine, pediatrics, and cognate subjects. The principle articles discussed in the present volume besides the two already mentioned are abortion by Professor W. Zangemeister of Königsberg abscess by Professor Klapp of Marburg, achylia gastrica by Professor I. Boas of Berlin acidosis by Professor H. Straub

² *Clinical Aspects of the Electrocardiogram*. By Harold E. B. Pardee M.D. Second edition. Revised. London: William Heinemann (Medical Books) Ltd. 1928. (Med. 8vo pp. xviii + 242. 60 figures. 25 s. net.)

³ *Low Blood Pressure Its Causes and Significance*. By J. F. Halls Dally M.D. B.Chir Cantab. M.R.C.P. London: William Heinemann (Medical Books) Ltd. 1928. (Demy 8vo pp. xix + 257. 15 figures. 15 s. net.)

of Creifswald acne by Professor A Buschke and Dr A Joseph of Berlin, Addison's disease by Professor H Zondek of Berlin, adeuoids by Professor G Funder of Berlin, diseases of the adnexa by Professor F Kirstein of Bremen, alcoholism by Professor G Binswanger of Kreuzlingen, allergy and anaphylaxis by Professor F Hansen of Heidelberg, diseases of old age by Professor H Curschmann of Rostock, anaemia by Professors P Morawitz and Carl Seifarth of Leipzig, angina pectoris and arterio sclerosis by Professor Ernst Neisser of Stettin, apoplexy by Professor G Klemperer and E Haase, arrhythmia by Professor Winterberg of Vienna, ataxia by Professor Frenkel Heiden of Berlin, ophthalmology in general practice by W Meisner, and the autonomous nervous system by F Claser. The text is freely interspersed with illustrations, some in colour. The articles, which are of a thoroughly practical and up to date character, angur vell for the success of the work.

In a little book entitled *Rheumatic Diseases*¹⁰ Dr M B Ray has succeeded in presenting us with an admirable survey of rheumatism. Like all other authorities on the subject he finds difficulty in finding a satisfactory classification, but his insistence on the wide variety of factors responsible for all these conditions does much to explain this difficulty. No one etiological factor is explanatory of their pathogenesis, therefore no one form of treatment can be effective, and the reader is especially warned against a too slavish belief in the efficacy of the removal of a septic focus.

Among the innumerable new societies for the promotion of health there is perhaps better justification for the formation of the Health and Cleanliness Council than for many of the others. This council concerns itself with the work of propaganda for a clean population believing that good health would follow. There is much to be said for the belief. Certainly there could be no difficulty arising in the teaching of hygiene in schools if it concerned itself with cleanliness. The council, with this intent, has issued a book¹¹ containing a series of outlines for lectures to be given by teachers in the elementary schools to their pupils. It has a foreword by Dr George Buchanan, medical officer of health for Willesden, chairman of the advisory board of the council, the authors of the book are Dr W A Muir, medical officer of health for Gillingham and Mr G H Green, lecturer in education in University College, Wales. They have done their work well. Their lessons are simple, sensible, and useful. A limited number of copies of this little book will be issued, on application to the society, free of charge.

The second volume of the twenty seventh edition of the late Professor STRUPPELL's textbook of pathology and therapeutics¹² has now appeared, and includes an index to the first volume, which we reviewed on September 22nd (p 532). The value of this textbook needs little reiteration in view of the well deserved popularity it has gained in previous years. The subject matter is comprehensive and attractively set out, the illustrations are clear and useful, and there is an appendix of therapeutical prescriptions.

One of the most suitable books on bacteriology for nurses and laboratory assistants is Dr EISENBERG's *Principles of Bacteriology*¹³. This book, the fourth edition of which we have before us, gives special attention to practical questions of applied bacteriology, and contains a brief description of the chief pathogenic bacteria. Besides minor alterations we notice that the chief changes made in the present edition are a new chapter on scarlet fever with information about the Dick test, a new chapter on tularaemia, and reference to recent work on measles.

COLE'S *Practical Physiological Chemistry*¹⁴ has now reached its eighth edition. The whole work has evidently been subjected to careful revision with a view to bringing the information well up to date. This is particularly the case with regard to the carbohydrates and the blood pigments and a description of a new potentiometer has been inserted. The practical value of this book is undoubted, and the new edition can be confidently commended to the notice of teachers and students.

PREPARATIONS AND APPLIANCES

THE ROTUNDA COT

DR BETHEL SOLOMONS, Master of the Rotunda Hospital, Dublin, sends a description of a special type of bed which has been devised by the pediatrician of the hospital, Dr Brian Crichton for use in the new infant ward. The accompanying illustrations give a general idea of the construction of this cot.

FIG 1.

and in Fig 1 the dimensions are indicated. In Fig 2, while the side A and the end B are shown up, A1 and B1 are let down half way, where they are supported by two iron bars which fold under the cot. These sides and ends can be

FIG 2.

lowered completely to lie parallel with the legs of the cot if required. The mattress, with an infant on it, can be drawn out on to a side or end, and an examination be made with ease. The infant need not be taken out of its cot for an examination, no stooping is involved, and no part is inaccessible for examination.

LIVER EXTRACT

The curative action of liver feeding in pernicious anaemia is one of the most remarkable advances made in therapeutics in the present century. One natural consequence of this discovery has been the production of numerous proprietary preparations of liver extract. The present situation is that methods of concentrating the active principle have been discovered but its chemical composition is unknown. The activity of liver concentrates can therefore only be estimated by prolonged clinical trials. It is consequently difficult to estimate the relative merits of the numerous extracts that are offered to the medical profession.

The latest extract we have received is termed hepatopson and it has been prepared by the Promonta Company Ltd, in collaboration with the medical clinic of Geheimrat Professor Dr Fr von Mueller of Munich. The makers claim that they have obtained a concentrate of which 1.25 grams are equal to a kilo of fresh liver. This claim represents a concentration considerably greater than that achieved by various firms of repute who have prepared such concentrations. The extract is sold in a diluted form— hepatopson liquidum—two tablespoonfuls of which are stated to be the equivalent of 200 grams of fresh liver. The makers state that hepatopson liquidum has been clinically tested in the Second Medical University Clinic, Munich (Professor von Mueller) and in the polyclinic of Professor Schottmueller in the Lippendorfer Hospital in Hamburg. Professors Schottmueller and Braun reported at the Congress of Physicians (Internists) in Wiesbaden that the preparation has shown good results as a specific treatment against pernicious anaemia.

THE STORY OF INSULIN

PROFESSOR BANTING'S CAMERON LECTURE

In the Cameron Prize Lecture, delivered at the University of Edinburgh on October 30th, Dr F G Banting of Toronto gave a most interesting account of the history of the research that culminated in the discovery of insulin.

Professor Banting said that he conceived the original idea on October 30th, 1920, after reading an article by Moses Baion which appeared in *Surgery, Gynecology and Obstetrics*, and in which the author pointed out the analogy between the degenerative changes which follow the experimental ligation of the pancreatic duct and the blockage of the duct by gall-stones. Later in the night, under the influence of ideas evoked by this article, he made the following entry in his notebook: "Ligate pancreatic ducts of dogs. Wait six to eight weeks for degeneration. Remove the residue and extract." The next step was the application to Professor J J R Macleod for permission to try these experiments in his laboratory, and for facilities for doing blood and urine sugar estimations.

Work began in May, 1921, and Dr C H Best, who was then a medical student, acted as assistant in the chemical work. The first attempts to ligature the pancreatic duct were partial failures, because the ligatures cut through the duct and the dogs had to be operated on a second time, but by July 27th degeneration of the pancreas was produced, and a saline extract of the degenerated pancreas was injected into a depancreatized dog. The blood sugar figure fell from 0.20 to 0.11 in two hours, and the clinical condition of the dog showed marked improvement. Another depancreatized dog was kept in good condition for eight days by the administration of extract from five degenerated pancreases. This, however, exhausted the available supply of "isletin," as the extract was then termed, and the dog rapidly became moribund. The idea was then conceived of exhausting the pancreas of a dog by continued injection of secretin, and then extracting the exhausted pancreas. This experiment was carried out, and the extract restored the moribund dog to a fairly normal condition. Important contributory evidence was thus obtained in favour of the main theory that the active principle was an extract of the island cells free from the products of the acinous cells.

The next task was to find an easier means of obtaining such extracts. The pancreas of foetal calves appeared to be a likely source, since these contained abundant islet tissue. It seemed reasonable to conclude that, since digestion is not called into play until after the birth of the animal, there would not be powerful digestive ferments present in the foetus. Experiment showed that extracts of foetal pancreas lowered the blood sugar of depancreatized dogs, and thus a cheap and plentiful source of isletin was discovered. It was also found that the active principle could be extracted from the foetal gland with acetone and alcohol, and that it was not destroyed by chloroform or ether. Alcoholic extracts of the pancreases of adult cattle were next made, and with various extracts a dog was kept alive for seventy days after removal of its pancreas.

On January 11th, 1922, the first patients were treated with pancreatic extract in the Toronto General Hospital. Following the injections there was a typical lowering of blood sugar and a slight decrease of the sugar in the urine. But on account of the high percentage of protein in the extracts a sterile abscess developed at the point of injection. These results were however, sufficiently encouraging to induce Professor J J R Macleod to turn a large proportion of his laboratory staff to work on the problems of the physiological activity of the pancreatic extract. Dr J B Collip developed a method of fractional precipitation by alcohol and produced a less toxic and more active extract. Finally, Dr Best took up the problems of production and refinement, and he is still in charge of the

production of insulin in the Connaught Laboratories at the University of Toronto.

Insulin was not the first name used among the group of workers. As early as August, 1921, the word "isletin" occurred in the notebooks. Professor Macleod insisted that the internal secretion of the pancreas should be called "insulin." Later it was found that Schafer of Edinburgh had suggested this name about 1910.

With a group of workers attacking various problems under Professor Macleod's directions, rapid progress was made. Quite early an attempt was made to find a test-tube reaction for determining the potency of insulin, but none was found. It therefore became necessary to develop a biological method of standardization. In the early work Collip had found that a normal rabbit given a certain dose of insulin developed in four hours a complex of symptoms characterized by intermittent convulsions and coma. The rabbit rapidly recovered when given injections of glucose, and could be used again for another test. It was therefore decided to use the rabbit in making a biological assay. The unit of insulin was defined as the amount required to reduce the blood sugar of a normal rabbit weighing 2.5 kg to 0.045 in four hours. To ensure a uniform unit of strength in the various countries the Public Health Committee of the League of Nations changed the definition as follows: The unit of insulin is one-third of the amount of material required to lower the blood sugar of a 2 kilogram rabbit which has fasted twenty-four hours, from the normal level (0.118 per cent) to 0.045 per cent over a period of five hours.

In May, 1922, in association with Dr Joe Gilchrist, a clinic was established in connexion with the Soldiers' Civil Re-establishment at Christie Street Hospital. A few months later clinics were established at the Toronto General Hospital and the Hospital for Sick Children. A number of private patients also presented themselves for treatment. The clinical value of insulin was now fully established, and the chief problem was to surmount the many and varied difficulties met with when large-scale production was attempted.

These clinical results were the outcome of years of patient, quiet effort of numerous workers in many fields of science. Insulin was but the final stage. It was known from the work of von Mering and Minkowski that diabetes was definitely associated with the pancreas, that if the pancreas was removed from a dog it became diabetic. It was also known from the work of Ssobolew that animals did not become diabetic when the acinous tissue had degenerated. The weight of evidence pointed to the existence of an internal secretion of the islet cells. A vast amount of scientific knowledge had accumulated on the subject of carbohydrate metabolism. Estimations of sugar in small quantities of blood and urine could be accurately made. Ketone bodies could be accurately estimated. Dietetic treatment for diabetes was highly developed. The world still owes a great deal to the diabetic patient for the development of dietetic knowledge which can now be applied to other diseases. The Toronto group of workers considered themselves fortunate in being able to add something of practical importance to the long series of previous investigations into carbohydrate metabolism.

The lecturer concluded with the following advice to the four or five hundred medical students who had listened to his story. The question may arise in the mind of someone present, what may I do? Do not enter upon research unless you cannot help it. Ask yourself the why of every statement that is made and think out your own answer. If, through your thoughtful work, you get a worthwhile idea it will get you. The force of the conviction will compel you to forsake all and seek the relief of your mind in research work. You can prepare yourself for work. The paintings of the great masters, the compositions of great musicians, the sermons of great preachers, the policies of great statesmen, and the campaigns of great generals do not spring full bloom from barren rock. Your training here is but a preliminary step in preparation for your life work. Mackenzie practised thirty years before he wrote his book on the heart. Training is required. As Osler says, "Live in a day's tight compartment, doing each

day's work well." If you are a true student you will be more dissatisfied with yourself when you graduate than you are now. It is not within the power of the properly constructed human mind to be satisfied. Progress would cease if this were the case. The greatest joy in life is to accomplish. It is the getting, not the having. It is the giving, not the keeping.

I am a firm believer in the theory that you can do or be anything that you wish in this world, within reason, if you are prepared to make the sacrifices, think and work hard enough, and long enough.

There is no chance, no destiny, no fate,
Can circumvent, can hinder or control
The firm resolve of a determined soul.
Gifts count as nothing. Will alone is great.
All things give way before it soon or late.

CONFERENCE ON "LIGHT AND HEAT IN MEDICINE"

A CONFERENCE on 'light and heat in medicine, surgery, and public health' was held in the buildings of the University of London at South Kensington from October 29th to November 1st. It took the form of twice daily sessions, at each of which a couple of papers on some application of the subject were read, and, when time permitted, discussed.

A few Continental visitors attended and added to the value of the programme. Dr FRANZ NAGELSCHUDD of Berlin gave two demonstrations. The first was a new method of diathermy application in which the electrode consisted of a thick layer of rubber so that the patient was not in contact with metal, and the danger of burning was practically eliminated. An advantage of the method was that treatment could be prolonged over a considerable period. The other demonstration was a method of applying external heat to the body by what he called 'foam treatment'. By adding a saponine solution to water of any desired temperature he was able to produce an air foam consisting of fine bubbles, and at a temperature depending upon that of the water from which it emanated. This foam he said, was of value in nasal irrigation, and also in treating vaginal discharge.

Dr W FLAEMER, chief assistant to Professor Wintz at the gynaecological clinic at Erlangen, discussed the use of light and heat in gynaecological practice. In most cases of vaginal disease this therapy had proved of great value, though only in combination with the conservative remedies. It had not proved satisfactory in uterine inflammation due to growth, but, combined with careful massage, it had achieved success in cases of enlarged or congested uterus resulting from certain misplacements. Light and heat had also proved efficacious in the treatment of amenorrhoea and dysmenorrhoea though only when there was general as well as local treatment and constant medical supervision.

Another foreign visitor Dr A J CEMACH of Vienna, discussed the uses of ultra violet radiation in oto-rhino-laryngology. As long ago as 1919 he had shown that middle-ear tuberculosis could definitely be influenced by light. Later he had developed a method of local irradiation of laryngeal tuberculosis from a quartz lamp. He now used quartz lamp irradiation exclusively where phototherapeutic treatment was indicated. Laryngeal tuberculosis was by far the most important of the processes accessible to light treatment, and he found that the desired reaction was most simply and rapidly produced by direct quartz lamp irradiation of the larynx.

A candid and philosophic survey of actinotherapy in certain skin affections was given by Dr W J O'DONOVAN. He said that one of the striking things in the history of light treatment had been the widespread recommendation of its use in eczema, in startling contrast to the scanty references to that disease in standard dermatological textbooks. The explanation of this, and possibly of similar circumstances, was that men who had taken up light therapy, though probably up to date in physics and in one or two branches of medicine, may not have acquired the precise dermatological nomenclature when they left medical schools before the great war. Cures of acne rosacea by means of ultra violet radiation had been reported, but such cases were recognized by the dermatologists to be most intractable. Very little reference to alopecia areata could be found in major textbooks on skin diseases, here, again, the value of local light therapy was much stressed. Apart from those cured by suggestion therapy, there would remain a large number suffering

from alopecia areata who would need ultra violet therapy to the whole body because of its tonic effect, rather than as a substitute for rubefacient liniment to a bald and otherwise healthy arc of the scalp.

Mr T TALBOT spoke on actinotherapy in dental caries, arguing that the determining factor in the arrest of caries was something additional to vitamin, and that there was evidence that this factor was produced by the action of ultra violet radiation on the skin. He had been impressed by the improved appearance of the teeth in some children who had been regularly exposed to a carbon arc lamp in a convalescent home.

Sir HENRY GAUVAIN exhibited a most entertaining cinematograph film, illustrating not only the general routine at the Sir William Treloar Home at Alton and Hayling Island, but also the technique pursued in the artificial light department, the preparation of the patient for local treatment, and so forth, but he insisted that light was only part of the treatment of surgical tuberculosis. With regard to particular methods he expressed himself a great believer in the value of the plain carbon arc.

The treatment of chronic pulmonary tuberculosis by light was broached by Dr M. WEINBERG of Mount Vernon Hospital. He said that good results were claimed for light in every other manifestation of tuberculosis, but in pulmonary it was said to be contraindicated. Numerous authorities, however—though few in England—had reported excellent results in the pulmonary condition. Amongst the thousands of cases of surgical tuberculosis already treated there must be many with quiescent pulmonary lesions, and if these had become active under light treatment it would surely have been noted. He agreed as to the unwisdom of applying light treatment where there was a marked toxæmia, but this would contraindicate ultra violet radiation in any condition. He exhibited a table showing the results of treatment on a number of patients with chronic disease by means of gradually increasing exposures to a 30 ampere carbon arc. Of the group of inpatients treated 25 had been sputum positive, 9 of these became sputum negative, and there was a gain in weight in all but a few. The outpatients were of a very poor and unfortunate class but 3 out of 14 who were sputum positive became sputum negative, and a number put on weight, while not one of the 24 who were sputum negative at the beginning became sputum positive under treatment.

Other speakers were Dr KERR RUSSELL and Dr C B HEALD, who both spoke on the development of apparatus, the one for actinotherapy and the other for electrotherapy, and there were a number of papers on photo-sensitization and on the biochemical aspects of the subject. The exhibition, which was opened by Sir JOHN SNELL, with Dr F E FREEMANTLE, M.P. in the chair, illustrated the great variety of lamp models and outfits now on the market and included some interesting demonstrations, such as the detection of ringworm infection by filtered ultra violet rays, an apparatus for the irradiation of milk to promote its vitamin D content, the influence of a quartz mercury vapour lamp on plants and the organization of the Bermondsey municipal solarium.

DANGEROUS DRUGS ACTS

THE Home Secretary, in a circular issued on November 2nd, gives notice that, under the Rules Publication Act 1893 he proposes, after the expiration of forty days, to make Regulations under Section 7 of the Dangerous Drugs Act, 1920 (10 and 11 Geo 5, cap 46), controlling the manufacture, sale, possession and distribution of the drugs to which Part III of that Act applies.

The principal objects of the Regulations are (1) To consolidate into one code the provisions of the seven separate acts of Regulations at present in force (2) To apply the provisions of the existing Regulations to the drugs and preparations which have recently been brought under Part III of the Act of 1920—namely, extract and tincture of Indian hemp, dihydrocodemone, dihydrocodeine, and preparations containing them, and preparations containing less than 1/10 per cent of diacetylmorphine.

Provision is also made for the constitution of a tribunal (similar to that which has already been constituted for medical practitioners in accordance with the recommendations of the Departmental Committee on morphine and heroin addition) to which the Secretary of State may refer any case where there is reason to think that a dentist may be contravening the provisions of the Regulations with respect to the supply, administration or prescribing of dangerous drugs.

Draft copies of these Regulations may be obtained on application to the Under Secretary of State, Home Office, Whitehall London S.W.1.

British Medical Journal.

SATURDAY, NOVEMBER 10TH, 1928.

HEALTH ADMINISTRATION AND POOR LAW REFORM

THE last session of the present Parliament has just opened, and its chief business will be to consider the proposals of the Government for the redistribution of the functions of local authorities, especially those concerned with highways, health, and Poor Law administration, and for financial grants and adjustments connected therewith. The financial way was prepared in this year's budget, and every part of the Government scheme, which is intended to be taken as a whole, has its importance, but the attention of the medical profession, as such, will naturally be concentrated on those proposals which affect the health services and hospital administration. These proposals are of vital importance, and upon the way in which they are moulded and carried into effect will depend, in large degree, the whole future of public health services of institutional provision for the sick, and of many medical professional interests and developments. Too much care, therefore, cannot be given to their consideration.

The exact form of the Government bill is not known at the moment of writing, but there is material from which its main features may be gathered and stated with some confidence. In the *Journal* of July 7th last (p. 23) we commented on the Parliamentary Paper in which the Government's proposals for Poor Law and other local government reforms were submitted in outline for the observations of local authorities and others. The medical aspects of these proposed changes were expounded afresh in an article on October 27th (p. 765). Correspondence between the Ministry of Health and the special committee of the British Medical Association which was set up to deal with this matter has shed further light on some of these. In addition the Royal Commission on Local Government has just issued a second report dealing with five special points on which its opinion was asked by the Ministry of Health, and it is significant that on all these points the Royal Commission was able to agree, apparently unanimously, with the suggestions which had been made by the Ministry. A summary of this report was given in last week's *Journal* (p. 800), and it is to be expected that the proposals therein contained with regard to the reorganization of areas, the extension of the local area for charge of certain services, the stimulation of unwilling or defaulting authorities, accelerated progress towards whole time appointments of medical officers of health, and the distribution of certain functions between local authorities, will all be incorporated in the Government bill. On all these matters, especially the last two, memorandums were presented to the Royal Commission by the British Medical Association. One such memorandum was published in the Supplement of May 1st, 1926 (p. 172), and another in that of September 29th last (p. 142). Upon the facts, statements, and proposals made in these two documents the policy of the Association is based.

At the present stage the important things are that the medical profession should properly appreciate the position and be fully informed as to the proposed

changes, and that it should concentrate on a few points in which modification is essential if grave danger to the health services and to the efficiency of hospitals is to be avoided. It is proposed that the Poor Law guardians shall be abolished, and that the whole of their functions—assistance, educational, health (including, of course, the control of hospitals and other institutions)—shall be transferred to the councils of counties and of county boroughs. It is proposed that each such council shall, between the passage of the Act and April 1st, 1930, submit to the Minister of Health for his approval a scheme in accordance with which it proposes to arrange for the administration of the transferred functions. It is proposed to establish a system of Government grants on a new basis, so that efficiency of administration under these schemes shall be encouraged or secured. There are thus three stages—the legislative stage, the scheme stage, and the grant stage—in which it may be possible for the medical profession to advise or to press the Government, the local authorities, or both, in order to secure its objects. At first sight the complete liberty of county councils or county borough councils as to the character of the administrative schemes which they may propose for approval is attractive. But unless certain compulsory features are imposed by legislation there is an obvious danger that many of these schemes may be inefficient in practice. It should be made compulsory for the council to distribute the transferred functions to suitable committees, and not to be content to set up merely another committee to which all these functions are to go *en bloc*. It should be made compulsory for a county council in whose area there are boroughs or urban districts of suitable size and experience to delegate to the councils of such county districts all functions similar to those which these districts are already concerned in administering, if such functions cannot be transferred directly to such districts. These two points are not primarily medical in character, though the profession is seriously concerned with them, inasmuch as experience shows that only in this way can effective health services be carried on without much waste and overlapping.

Of more immediate medical concern are two other points. It ought to be made compulsory that the transferred health and hospital functions should be dealt with through a statutory committee established on the lines of the existing education committees—that is, in accordance with an approved scheme providing that such committee should contain not merely a majority of members of the parent council, but also other persons experienced in the work required, including members of the medical profession. There might be separate health and hospital committees, or a hospital subcommittee of the health committee, or a separate responsible governing body for each hospital, but in all cases the compulsory co-optation of experienced persons is essential. Without it there will almost certainly be in most cases either inefficient administration through lack of experience or bureaucratic administration through necessary reliance on the sole advice of medical and other officials. There should be compulsory established also in each area a statutory local medical advisory committee, which the council should be obliged to consult on all medical professional matters, and whose opinion should be available on all other health or hospital matters coming within the province of the council. All these points can best be secured by legislation. In order to secure them it is evident that considerable pressure will have to be brought to bear upon the Minister of Health and

on members of Parliament, for the method of permission and not of compulsion is obviously the easier for the legislator, and may be advocated with much plausibility. If legislation should fail it may still be possible to achieve much by inducing councils of local authorities to embody these features in their schemes, or by pressing the Minister not to sanction schemes which do not include them. It remains, however, the first duty of our profession, in the interests of the public health and of satisfactory hospital control and co-ordination, to use its utmost endeavour to secure these essentials of efficiency during the legislative stage.

THE AGE OF NOISE

Will noise destroy our civilization or will our civilization destroy noise? We are living in an age of noise, but of noise that has worked itself into the texture of life so insidiously that many people are still unaware that any change has taken place at all. It is a curious fact about human beings in the mass that they are seldom aware of doom until it has overtaken them. They are blind to the writing on the wall. They do not even hear the blast of trumpets and the shouting, they only gather themselves up a little surprised when the walls have unaccountably tumbled about them. There appears, indeed, to be no limit to man's capacity for adapting himself to noxious influences once he regards them as inevitable. If he is not deafened by the increasing noise in our society he can shut his ears to it. Some people, indeed, make a pleasure of necessity, and cry out for more and bigger noises. In the stillness of the evening, if such an anachronistic term may be permitted, they switch on the "loud speaker" or grind noisy tunes from the gramophone. They have even evolved jazz a cacophony generally regarded as symptomatic of the age we live in. It is as though the stresses of life were so unendurable that they must make a great noise to keep their spirits up. Children, it is believed, like to bang a drum, not because they are so misguided as to enjoy the sound of it, but because it is an activity that ministers to their self importance. It enables them to produce a tremendous effect without much effort. They discover for themselves that noise is a symbol of power—a fact expressed admirably in the popular term describing an important person as 'the big noise'. It is permissible to speculate whether it is a sense of frustrated power, a teasing inferiority complex, that drives the motorist to substitute the klaxon horn for the drum, whether, indeed, the pandemonium of whistles and hand rattles, fireworks and bugles, apparently indispensable to the happiness of great masses of people making holiday together, may not be equally symptomatic of regression to an infantile state.

In one of his Utopian romances Mr H. G. Wells suggests that a commonly overlooked cause of man's inefficiency lies in the fact that much of his energy is used up in an incessant war on bacterial invaders. In our delight at his frequent victories we are apt to overlook the price he must pay for them. We forget that throughout his life he is forced, albeit unconsciously, to divert to the task of creating antibodies and other bacterial principles a great deal of physiological energy that, in the absence of bacteria, could be more profitably devoted to creative ends. Needless to say, in Mr Wells's Utopia the problem is solved by the simple expedient of abolishing pathogenic bacteria altogether. A somewhat similar suggestion, but about man's war against noise, is made in a document that no one would seriously describe as Utopian,

we refer to the British Medical Association's Memorandum on Noise submitted on October 23rd to the Ministry of Health, and published in the *Supplement* to our present issue at page 209. This most readable memorandum suggests that too much may be made of the fact that workers engaged in industries in which work has to be done to the accompaniment of the noise of machinery appear to enjoy good health. It argues that the employment of energy for inhibiting nerve-racking noises must involve an inevitable loss of personal and industrial efficiency. Adaptation to noxious influences may occur smoothly and unconsciously, but this must not be taken to imply that it is achieved without effort, the individual may, in fact, be as unaware of the habitual strain as he is of the habitually inhibited stimulus. Workers in noisy industries acquire a capacity for hearing even the faintest whisper through the din that surrounds them. This is a very pretty talent, but it cannot be said to compensate completely for the price that must be paid to develop it. The prevention or reduction of noise in commercial work is, as Professor Spooner has said, a paying proposition. Noise is one of the heaviest overhead costs in industry.

The multitudinous sounds of the big city differ, however, in many respects from the industrial noises just considered. The latter are usually continuous and uniform, they do not, like a lorry in the night, burst in with the suddenness of an explosion, and the worker can brace himself to meet them. The former, on the contrary, are discontinuous, discordant, and un-rhythmic, various in quality, pitch, and intensity, above all, they are sudden and aggressive. The investigations of Dr J. B. Watson have shown sudden noise to be one of the two stimuli capable of provoking fear reactions in a child whose reflexes are as yet unconditioned. Most of us, from personal experience, know that this quality is retained throughout life. The frequent stimulation of this primitive reflex in a healthy person not engaged in an exacting occupation may produce nothing more serious than distraction and annoyance—perhaps a deep felt desire to do physical violence to the author of the noise in question. But in the sick and convalescent, in the man or woman trying to rest and sleep after the day's work, in the professional worker grappling with vital and intricate problems, and finally in the neurotic subject, it is bound to produce effects which no one concerned with the health, happiness, and efficiency of the people can afford to ignore. One may even concede Dr Millais Culpin's point that noise is never a direct cause of neurasthenia. Perhaps the symptom complex of fatigue, hyperacousis, irritability, and anxiety, so often observed in the worker deprived of regular sufficient sleep by aggressive noises at night, is not really neurasthenia at all, but a different disease of the same name. There can, however, be no doubt that noise does exacerbate, even if it does not produce, the difficulties of the neurasthenic subject (using the word strictly in Dr Culpin's sense). It tends to augment his anxieties and complicate his already too exacting problems of personal adjustment.

'It is a revolution, not a mere change of fashion, through which we are passing'. Unless something is done quickly to check the growing volume of sound that assaults our ears we may find ourselves deprived more and more of that capacity for sustained work, for clear thinking, and energetic action which is the mainstay of civilized life. Much can be achieved by personal restraint and mutual consideration—it is a curious fact that our neighbours' noises are louder than our own—much by measures on the lines pro-

posed in the British Medical Association's memorandum. These proposals, it may be conceded, are extremely modest in scope, and should be taken to represent the bare minimum of what is needed to deal with the problem. The most vital among them—namely, the first and second—deal with the association between noise and speed, and in this connexion we may repeat what we said in a leading article in our issue of August 25th, that "unless speed on the roads can be effectively regulated—and all attempts to do so have hitherto notoriously failed—noise will continue." Attention may also be drawn to Professor Spooner's additional suggestions that horns or hooters should be standardized as to pitch, and that a low melodious note should be adopted, that worn ram shackle vehicles should be warned off the streets by the authorities, and that the designers of machinery should pay more attention to the balancing of rotating parts, particularly high speed ones, and to the mounting of certain machinery on anti-vibration supports in order to minimize the noise incidental to its operation. At present most of us would give almost anything for a quiet life.

FAT-SOLUBLE VITAMINS

THE discovery that the antirachitic vitamin can be produced artificially by the irradiation of ergosterol has led, as is only natural, to its production on a commercial scale, and a considerable number of proprietary preparations of irradiated ergosterol are now on the market. This development has resulted in certain problems assuming considerable practical importance. It is important to know, in the first place, whether irradiated ergosterol is a full substitute for cod liver oil, and, in the second place, whether excess of ergosterol is likely to produce harm. Irradiated ergosterol is the antirachitic vitamin in a very pure form, but cod liver oil contains both this vitamin and also vitamin A, which hitherto has been termed the growth promoting vitamin. Recent investigations by Green and Mellanby¹ in this country, and by Sherman and Burtis² in America, have established with fair certainty that an adequate supply of vitamin A is of great importance, because it is an essential for the maintenance of the power of the body to resist infection.

Green and Mellanby (as described by them in our columns three weeks ago) found with rats that deprivation of vitamin A resulted, in practically all cases, in a variety of infective and pyogenic lesions. Administration of vitamin D alone did not prevent the appearance of these lesions, but they were prevented by the administration of vitamin A. The authors therefore suggested that vitamin A might suitably be termed the anti-infectious vitamin. Sherman and Burtis found that a mild deficiency in vitamin A, no greater than might easily occur in a human dietary, was sufficient to cause a great increase in the incidence of infection in rats. These experiments show that vitamin A is a very important constituent of the dietary, and appear to justify the conclusion that irradiated ergosterol alone cannot be regarded as a full substitute for substances such as cod liver oil, which contain both vitamin A and vitamin D.

It has been pointed out that certain German workers have obtained results which indicate that

the power of the body to resist infection is influenced by the supply of vitamin D. This would accord with the well recognized fact that rickety animals and children are very susceptible to infections. These results do not, however, invalidate Mellanby's conclusion that deprivation of vitamin A causes septic infections of the upper air passages, lungs, and kidneys, and that these infections cannot be prevented by administration of vitamin D alone. Even if the matter were more doubtful it would obviously be wiser to keep on the safe side and to administer vitamins A and D combined rather than either of these alone.

The possibility that vitamin D may produce toxic effects is of considerable practical importance because it can be obtained in an almost pure condition, and the physiological daily dose for a human being is only a fraction of a milligram, hence overdosage can easily be produced. Kreitmair and Moll³ and Pfannenstiel⁴ found that excess of vitamin D produced severe toxic effects in laboratory animals. Dixon and Hoyle (whose paper appears in our present issue at page 832) failed to confirm this result. Harris and Moore⁵ found that a huge excess of irradiated ergosterol (one hundred thousand times the physiological dose) always killed rats, but that a moderate excess had no toxic action. They also quote the result of Hess and Lewis, who gave rickety children 2.5 to 5 mg irradiated ergosterol daily. This large dose did not produce toxic effects, but, on the contrary, the children benefited greatly.

The evidence shows, therefore, that irradiated ergosterol only produces toxic effects when given in enormous excess, and it may be concluded that poisoning by this substance is not a probable danger in clinical practice.

DAWSON WILLIAMS MEMORIAL PRIZE.

At the general meeting of subscribers to the Dawson Williams Memorial Fund, held on July 10th last under the chairmanship of Sir Humphry Rolleston, and reported in our issue of July 14th (p. 65), it was resolved that the sum subscribed to this memorial to our late Editor should be devoted to a prize in pediatrics, to be awarded every two years or at longer intervals at the discretion of the trustees, and that the scope of the prize and the details of its adjudication should be left also to their discretion, with the assistance of such other persons as they might wish to consult. The following were invited to act, *ex officio*, as trustees, and have agreed to serve: The Presidents (for the time being) of the Royal College of Physicians of London, the Royal College of Surgeons of England, the British Medical Association, the Royal Society of Medicine, the Section for the Study of Disease in Children of the Royal Society of Medicine, and the Editor of the *British Medical Journal*. The Medical Secretary of the British Medical Association, at the request of the subscribers, consented to act as convener and secretary of the trusteeship. The first meeting of the trustees was held at the House of the British Medical Association on October 19th, with Sir John Rose Bradford, F.R.C.P., in the chair. It was decided to ask the Charity Commissioners to accept for investment the sum of £849 now in hand, to receive all interest accruing therefrom, and to pay this over to the trust account at the bank for the purposes of the Fund. In pursuance of the resolutions of the meeting on July 10th, it was resolved that the Dawson Williams Memorial Prize should take the form of an award for the best work done in pediatrics during the five years

PROBLEMS OF LARYNGOLOGY AND RHINOLOGY

IN his presidential address on November 2nd to the Section of Laryngology of the Royal Society of Medicine Mr Bell Tawse touched upon "Some unsolved problems of rhinolaryngology." While some of the older problems, particularly those relating to malignant disease of the upper air passages and the oesophagus, still remain unsolved or unsettled, new problems have arisen out of modern surgical treatment. Among the latter perhaps the one most urgently requiring attention is the prevention and arrest of excessive haemorrhage following the complete enucleation of the tonsils. The president, observing "reports of this complication are very rare," pertinently asked "If it is an uncommon incident, why is there such a persistent effort to find a guillotine that will do the work bloodlessly?" Further, "If the loss of blood is negligible, why should there be such a variety of pressure clamps on the market?" It is common knowledge that a child is more seriously affected by haemorrhage than an adult, it is also common knowledge that a very large majority of the children never give any anxiety from bleeding, but, as the president remarked, "What about the others?" Association with a school medical service had opened his eyes to the serious effect on a child of undue loss of blood. In a series of 900 cases of enucleation of the tonsils by a blunt-bladed guillotine and the removal of adenoids under ethyl chloride anaesthesia, 18 cases—that is to say, 2 per cent—required the application of pressure clamps and ligature of vessels. The quantity of blood lost varied from 20 to 40 oz., and allowing for further loss in various ways and during the operation it was probably a good deal more. In 2 per cent of this same series haemostatics appeared to have obviated the necessity for operative intervention. In another series of 764 cases the percentages were very much the same. Nearly all these children had a protracted convalescence, and in the worst cases several months elapsed before complete recovery. Opinions are sharply divided on the point whether haemorrhage is more likely to occur after enucleation of the tonsil by dissection or after enucleation by the guillotine. The president expressed his opinion without any doubt that there is much less bleeding when the method employed is enucleation by dissection with ligature of the chief vessels. Unfortunately, on the one hand, there are not enough trained dissectors in the country, nor a sufficient number of skilled anaesthetists to deal with the huge lists of hospital cases, and, on the other hand, the bloodless guillotine has not yet been discovered, so this problem is still awaiting solution. Passing to malignant disease, Mr Bell Tawse submitted for inquiry the unsolved problem of how to determine when a case of intrinsic epithelioma of the larynx should be treated by thyrotomy or laryngectomy and appealed to those with leanings towards pathology to separate into definite clinical types the various degrees of malignancy, so that it might be possible to have reliable evidence that thyrotomy is just permissible in one case, risky in a second, and useless in a third. If ever there was a problem, he said, worthy of a man's life-work it was cancer of the oesophagus. The very thought of the locality immediately produced a feeling of surgical impotence. Radium and intensive x rays were said to palliate. A very few patients had survived transthoracic excision, and by that method a few cures had been claimed in foreign countries. Speaking for himself, he had never seen a cure of malignant disease of the oesophagus. The address concluded with some comments, perhaps long overdue, on the so-called status lymphaticus. Why does the coroner's

verdict of death from status lymphaticus evoke sympathy from all, and dubiety from some? The case is frequently one of tonsils and adenoids, and we are told there is no known means of detecting the condition during life, and that the patient would have died during any other operation, meaning, presumably, that the anaesthetic is the cause of death. Mr Bell Tawse asked three questions. *Would the patient have died?* Is there any pathological lesion to be detected during life? How are we trying to solve the mystery if there is one? Some few months ago, under ether and chloroform, he performed tracheotomy on a boy of 5 whose tonsils and adenoids he had removed five weeks previously under ethyl chloride. The thymus completely hid the cricoid and trachea, and had to be forcibly retracted. *Post-mortem* examination three weeks later revealed an enormous thymus continuous with a mass of similar tissue, and enveloping the trachea, the bronchi, the roots of the lungs, and the heart, and yet this child was not upset in any way by either anaesthetic.

INTERNATIONAL CONTROL OF THE DRUG TRAFFIC

IN describing the activities of the League of Nations Assembly at its last meeting in September, our correspondent at Geneva, in the *Journal* of September 28th (p. 578), referred to the increased attention given to the traffic in opium and other dangerous drugs by that body, and mentioned that the League Advisory Committee on Traffic in Opium would, at its next session, examine a scheme for the limitation of the manufacture of drugs transmitted from the United States Government. We have now received from the Anti Opium Information Bureau (a non-official organization) a memorandum giving details of these proposals, which are described as a "scheme of stipulated supply." The memorandum states that the present problem arises mainly from the over-manufacture of opium derivatives and cocaine, and only in a much lesser degree from the smoking or eating of opium. Further, it is alleged that, while manufacturing countries pledged themselves to limit output in 1912 and 1925, none has apparently enforced any system for direct limitation, and that the drugs continue to be produced in quantities greatly in excess of the world's legitimate requirements. It is recalled that the Advisory Committee has repeatedly taken the view that the only method by which this traffic can be brought to an end is by a limitation of the manufacture and by stricter international control, and Sir John Jordan is quoted as saying "The Governments should stop the excessive production, which they could do perfectly well if they were honest and efficient." In the meanwhile, it is said, manufacturing countries plead the absence of any known equitable scheme for apportioning among them the world's legitimate medical and scientific requirements. The scheme outlined essays to supply this deficiency. In the introduction to the scheme an estimate is referred to which states that "at least ten, perhaps fifty, possibly hundreds of times the world's legitimate need for these narcotics is being poured out of the drug factories," and it is added that the drugs are all produced in about forty factories, located in eight countries. Seven of the forty factories, the memorandum states, virtually all of whose products reach legitimate destinations are in the United States, Great Britain, and India, the remainder are in Germany, Switzerland, France, Holland and Japan, and from them the illicit trade is almost exclusively supplied. The problem, therefore, is stated to be to co-ordinate the export trade of the producing countries with the requirements of the non-manufacturing countries. Figures are already available giving a reasonably accurate estimate of the world's per capita requirements of manufactured drugs, and the scheme assumes that, while conditions vary considerably from one country to another,

these are adequate to reveal any glaring discrepancy between legitimate requirements and an over-statement by any country. It is claimed that the scheme would impose only two new commitments on countries adhering to it. These are (a) the modification in advance, for a determined period, of their requirements of each substance derived from opium and the coca leaf now or in the future covered by either the Hague Convention or the Geneva Convention, and (b) a statement of the country from which they will purchase their requirements. The information so gained should disclose the volume of the legitimate trade of each country manufacturing or re-exporting narcotic drugs. This, it is contended, would overcome the weakness of the present system, under which every manufacturer is free to compete for the trade of all the world's non-manufacturing countries. The scheme, it is maintained, conforms juridically with both Conventions, as, while securing the essential collective action, it does not require countries to commit themselves specifically to more than the present individual action. In meeting the possible criticism that this scheme does not prevent over-production in manufacturing countries, it is assumed that the Governments concerned are above the suspicion of conniving at such over-production, and that they would probably take steps to ensure the restriction of raw material imports to the amounts necessary for known legitimate requirements only. It is suggested that economic pressure might be brought to bear on any country outside the scheme in which a "pirate" factory was established. The memorandum concludes that a new conference is required to secure the execution of the scheme, and that the members should be persons distinguished for their ability to apply to the practical task in hand "the utmost intelligence, common sense, and business sagacity," and who "are not restrained by the political considerations of the country which they represent that have heretofore prevented them mutually from exposing each other's full and notorious guilt." The desire of the authors of the memorandum is to see the drug problem removed from the political sphere of diplomatic bargaining, and treated as a supra national question. It may be noted that the new Spanish law on narcotic drugs embodies the same principle as this "scheme of limitation", the Spanish Government presumably intends to make known its requirements and to indicate the source from which it will obtain its supplies. The Anti-Opium Information Bureau points out that in the *British Medical Journal* of September 29th, in the article to which we referred above, it was mentioned that "no exports of opium from India would be allowed after 1934," and states that this refers only to exports destined for the manufacture of opium prepared for smoking. It is added that as an offset to the reduction of exports for this purpose there should be taken into consideration the fact that exports for medical purposes (shipped to the High Commissioner for India in London) are considerable, and that as a result of special efforts the morphine content of the opium being produced in India is increasing.

MSS AT THE COLLEGE OF SURGEONS

THE Royal College of Surgeons of England has done well to publish a catalogue of manuscripts in its library. Its librarian, Mr Victor G Plarr, tells us in his preface that this catalogue does not contain the titles of the John Hunter manuscripts already set out in J B Bailey's "List of Books, etc., relating to John Hunter," but it records the titles, or the descriptions when titles were not traceable, of all other written documents in the collection. Besides more modern documents, many of these writings have been rediscovered in outlying parts of the College house, and many owe their existence to the industry of a former conservator, William Clift. Being, as Mr Plarr

states, the first complete record of the Clift, Cooper, Jastor, Owen, Paget, Quekett, and Simon papers, the catalogue furnishes the key to much information not generally available on the history of the College departments. Type-written papers, paintings, and drawings are not recorded in it. Perusal of this catalogue provides hints of a very olla podrida of information on surgical and anatomical subjects. There are MS notes and abstracts of Abernethy's lectures at St Bartholomew's, some of them in the MS of Dr P M Latham. The list of Clift papers occupies ten pages, and the Hunter Baillie papers, some of which formed recently the subject of a Nova et Vetera paper in our columns by Mr Plarr, well deserve cataloguing. Under the heading of "Hillman" we find a neologism (or is it archaism?), "reputup." At first sight this suggests some primitive Polyesian language, but it refers to the re-mounting of a specimen. We wonder if this convenient word will find admittance to the next supplement of the *New English Dictionary*. John Napier's "Diary of a Resurrectionist," which Mr Plarr's predecessor so learnedly described and commented on, is included in this catalogue, and so also is a most suggestive title, "Letter from A Copland Hitchcouson to Joshua Brookes, relating to lonely churchyards and the possible supply of bodies for dissection in the West Highlands (1825)." This entry reminds us how far afield anatomists were obliged to go for materials for anatomical teaching before the passing of the Anatomy Act. Brookes, of course, was the celebrated head of the Blenheim Street school. There is an interesting MS, dated 1621, in which Mayerne gives an account of his family. This is the physician whom Judge Puiry, in a recent book, has most unjustifiably accused of supplying poison for the murder in the Tower of Sir Thomas Overbury in 1613. Quite a number of MS reports of the lectures of Monro secundus have been presented to the College through the Guildhall librarian. Two pages are taken up with the list of Richard Owen's MSS, and we are reminded how much work Sir James Paget did in pathology by the fact that the list of his papers occupies three pages. Those of Sir John Simon also occupy much space. It will perhaps be a surprise to many readers to know what a wealth of MSS the College possesses, and the printing of this catalogue should help to put that wealth at the service of students of surgery, anatomy, and pathology. The title page gives no hint as to whether the catalogue is for sale, or if not, how copies can be obtained.

THE EFFECT OF HIGH TEMPERATURES ON THE MINER

THE atmospheric conditions in hot and deep mines formed the subject of an interesting discussion at the annual meeting of the Institution of Mining Engineers, held in London at the end of October. It arose on a paper by Mr David Peuman, D Sc, principal of the School of Mines at Dhanbad, India, who stated that the Indian collier frequently had to work in a mine with a wet-bulb temperature of 85° F, or even higher. Moreover, the air in most of the working places in Indian mines is practically still, or at the best very sluggish, yet the miners work day after day uncomplainingly, and not only without mishaps, but apparently without any ill effects. It is well known that persons accustomed to hot damp air are able to work with comfort under hygrometric conditions which would be very trying to men who had not been acclimatized, and Mr Penman thinks it may be that the acclimatization of the Indian enables him to withstand heat in coal mines better than the average white man. The Indian miner, indeed, prefers to work in a warm place. He likes a gallery in which the temperature is, say, 75° F better than one in which it is 50°. Nor does he like to work in a strong breeze. He wears practically no clothing, whether the mine

atmosphere is warm or cool, thus his whole body is exposed to the drying and cooling action of the air. He also works irregularly, remaining at work for about an hour, and then resting in a cooler place for fifteen minutes or more. While actually at work he is a hard worker, though probably he does not work at a rate equal to that of the British collier. He is, as a rule, shorter in stature and of much lighter build, and consequently expends less energy in physical exertion. But he dislikes any change in the temperature conditions to which he is accustomed, and would resent transfer from a place where the temperature is, say, 88° F and the humidity 98 per cent, to a place where the temperature is 20° lower. Dr J S Haldane said that his experience of deep submarine workings off Cornwall, where very high temperatures were registered, was very like that described by Mr Penman, the men in those workings remained there for a short time, and then came out and cooled down, usually under a jet of compressed air. They were exceptionally healthy in spite of the conditions under which they laboured, and did not seem to mind their warm situation. He himself had found it very difficult to remain when the wet-bulb temperature was over 80°, and if the air was perfectly still the limit of endurance was about 88°. A mining engineer from the Rand, Mr James Whitehouse, mentioned that in some of the gold mines there men had to work at a very high temperature, although the ventilation was extremely good. But the African natives appeared to be less happy in the mine than the Indians, perhaps because, though equally inured to hot conditions, they were less accustomed to humidity. A number of them went down with heat apoplexy, these being almost invariably men who had gone straight from their homes into the mine without being acclimatized. It was now a rule on the Rand that the miners should stay for a month in the upper workings, where conditions were less strenuous. Most of the cases of heat apoplexy had proved fatal, until recently a preparation made in Germany, and known as "lobleine," was introduced, injections of which had been the means of saving a good many lives. Dr Haldane further stated that in his experience of mines in this country he had come across only one case of heat-stroke, this was in a man who was assisting in rescue operations after the disaster at Hamstead colliery. The wet-bulb temperature there was about 85° F, and the man was wearing a flannel shirt. Evidently under the pressure of rescue operations he failed to adjust himself to the temperature conditions—as the white man at least could generally be trusted to do—and died of apoplexy.

"THE CRIPPLE."

WE announced a few weeks ago that with the October number the name of *The Cripples' Journal* would be changed to *The Cripple*, and that the scope and aims of the periodical would have a great extension. The October number has lately appeared, and we may say at once that the bold adventure which this change signifies is likely to be fully justified by results if future numbers are as interesting and important as this. When the journal first started its interests seemed mainly to be those of hospitals for cripples and the treatment of deformities, but the new periodical takes not only an international view, but includes practically all that concerns the care and education of cripples and the prevention of deformity in its widest sense as its province. As Mr Watson says in his editorial notes: "It is a vast ambition, because its lines of demarcation are so vague." All the more, therefore, if the new journal is successful, will its achievements be far-reaching. Prevention, treatment, training, and rehabilitation—these are the great subjects to be studied and furthered all over the world. Not only is attention to be paid to the unfortunate owners of damaged limbs, to whom the term "cripple"

has usually been restricted, but also those with hearts crippled by rheumatism and with lungs damaged by tuberculosis. As an instance of this extension of the meaning of the term we would cite the very interesting instalment of an article by Dr P G Varrioi-Jones on village settlements, with a foreword by Sir Robert Jones. The author writes with authority on the subject of the Papworth settlement, which owes so much to his vision and ability. Sir Robert Jones points out the desirability and difficulty of recognizing the onset of tuberculosis in its earliest stages, and the danger of allowing so-called cured or relieved cases of pulmonary disease to return to family life, only to spread infection. Further study and research are necessary before we can hope to arrest tuberculosis in its beginning, but the success of such settlements as Papworth points the way to the prevention of reinfection by returned cases. Sir Robert Jones suggests, indeed, that "the solution of most of the medico-social problems of our day will be found in prophylaxis for the fit and village settlements for the unfit." More than half of this first number of the new series consists of an educational supplement, in which is to be found a great deal of interesting and valuable information on education for crippled children and special schools in Britain, and on the position in America, where, since the war, organizations have developed, and are still developing, having for their objects the welfare of cripples in the widest sense of the term. Not only are the various State legislatures engaged in helping charitable organizations, but the Federal Government also helps with money in certain cases. To realize what has to be done it is only necessary to mention that it is estimated that there are 2½ million cripples under 16 to every 1,000 of the population, making the shocking total of over 300,000 in the United States.

THE STAGE DOCTOR

A LIGHT-HEARTED evening, if not a very instructive one, was provided by the Hunterian Society of London on November 5th, at Cutlers' Hall, when the curtain went up on a discussion on "Doctors and the stage." Two of the promised "stars," Dame Madge Kendall and Dr Harold Deniden, failed to take their parts, but the under-studies rose to the occasion. The prologue was spoken by Mr William Devereux, the actor and dramatic author, who confessed that during his forty years on the stage he had played the part of doctors without knowing anything about medicine, his cue was to look preternaturally wise and to affect a bedside manner. Lady Simson (Miss Lena Ashwell) said that she could not remember appearing in a part in which a doctor was represented, and the only play of recent years with any extensive medical interest which she recalled was *The Doctor's Dilemma*, by Mr George Bernard Shaw, of this she had evidently a poor opinion, saying that in its dazzling display of fallacies it matched the most recent work of the same author, *The Intelligent Woman's Guide to Socialism*. Sir St Clair Thomson contributed to the discussion an analysis he had made of the allusions to the profession in the plays of Shakespeare, in which the physician appeared seven times and the surgeon not at all, although the barber-surgeons were a corporate body in Shakespeare's day. Portia, however, bade Shylock "Have by some surgeon," and Lear called for surgeons—"I am cut to the brains." Until he produced *King Lear* in 1606 Shakespeare had rather made fun of the profession, but in that play the doctor emerged as an honourable and sympathetic character, possibly Shakespeare's prospective son-in-law—his daughter was married to Dr Hall of Stratford-on-Avon in 1607—had opened his eyes. In *Pericles* there was to be found as noble a panegyric on the profession as had ever been uttered on the stage. The representation of the profession in contemporary plays was the subject of some amusing

these are adequate to reveal any glaring discrepancy between legitimate requirements and an over-statement by any country. It is claimed that the scheme would impose only two new commitments on countries adhering to it. These are (a) the modification in advance, for a determined period, of their requirements of each substance derived from opium and the coca leaf now or in the future covered by either the Hague Convention or the Geneva Convention, and (b) a statement of the country from which they will purchase their requirements. The information so gained should disclose the volume of the legitimate trade of each country manufacturing or re-exporting narcotic drugs. This, it is contended, would overcome the weakness of the present system, under which every manufacturer is free to compete for the trade of all the world's non-manufacturing countries. The scheme, it is maintained, conforms juridically with both Conventions, as, while securing the essential collective action, it does not require countries to commit themselves specifically to more than the present individual action. In meeting the possible criticism that this scheme does not prevent over-production in manufacturing countries, it is assumed that the Governments concerned are above the suspicion of conniving at such over-production, and that they would probably take steps to ensure the restriction of raw material imports to the amounts necessary for known legitimate requirements only. It is suggested that economic pressure might be brought to bear on any country outside the scheme in which a "pirate" factory was established. The memorandum concludes that a new conference is required to secure the execution of the scheme, and that the members should be persons distinguished for their ability to apply to the practical task in hand "the utmost intelligence, common sense, and business sagacity," and who "are not restrained by the political considerations of the country which they represent that have heretofore prevented them mutually from exposing each other's full and notorious guilt." The desire of the authors of the memorandum is to see the drug problem removed from the political sphere of diplomatic bargaining, and treated as a supra-national question. It may be noted that the new Spanish law on narcotic drugs embodies the same principle as this "scheme of limitation", the Spanish Government presumably intends to make known its requirements and to indicate the source from which it will obtain its supplies. The Anti-Opium Information Bureau points out that in the *British Medical Journal* of September 29th, in the article to which we referred above, it was mentioned that "no exports of opium from India would be allowed after 1934," and states that this refers only to exports destined for the manufacture of opium prepared for smoking. It is added that as an offset to the reduction of exports for this purpose there should be taken into consideration the fact that exports for medical purposes (shipped to the High Commissioner for India in London) are considerable, and that as a result of special efforts the morphine content of the opium being produced in India is increasing.

MSS AT THE COLLEGE OF SURGEONS

THE Royal College of Surgeons of England has done well to publish a catalogue of manuscripts in its library. Its librarian, Mr Victor G Plarr, tells us in his preface that this catalogue does not contain the titles of the John Hunter manuscripts already set out in J B Bailey's "List of Books, etc., relating to John Hunter," but it records the titles, or the descriptions when titles were not traceable, of all other written documents in the collection. Besides more modern documents, many of these writings have been rediscovered in outlying parts of the College house, and many owe their existence to the industry of a former conservator, William Clift. Being, as Mr Plarr

states, the first complete record of the Clift, Cooper, Lister, Owen, Paget, Quekett, and Simon papers, the catalogue forms the key to much information not generally available on the history of the College departments. Type-written papers, paintings, and drawings are not recorded in it. Perusal of this catalogue provides hints of a very olla podrida of information on surgical and anatomical subjects. There are MS notes and abstracts of Abernethy's lectures at St Bartholomew's, some of them in the MS of Dr P M Latham. The list of Clift papers occupies ten pages, and the Hunter Baillie papers, some of which formed recently the subject of a *Nota et Vetera* paper in our columns by Mr Plarr, well deserve cataloguing. Under the heading of "Hillman" we find a neologism (or is it mischievous), "reputup." At first sight this suggests some primitive Polynesian language, but it refers to the re-mounting of a specimen. We wonder if this convenient word will find admittance to the next supplement of the *New English Dictionary*. John Napier's "Diary of a Resurrectionist," which Mr Plarr's predecessor so learnedly described and commented on, is included in this catalogue, and so also is a most suggestive title, "Letter from A Copland Hutchinson to Joshua Brookes, relating to lonely churchyards and the possible supply of bodies for dissection in the West Highlands (1825)." This entry reminds us how far afield anatomists were obliged to go for materials for anatomical teaching before the passing of the Anatomy Act. Brookes, of course, was the celebrated head of the Blenheim Street school. There is an interesting MS, dated 1621, in which Mayorne gives an account of his family. This is the physician whom Judge Parry, in a recent book, has most unjustifiably accused of supplying poison for the murder in the Tower of Sir Thomas Overbury in 1613. Quite a number of MS reports of the lectures of Monro secundus have been presented to the College through the Guildhall librarian. Five pages are taken up with the list of Richard Owen's MSS, and we are reminded how much work Sir James Paget did in pathology by the fact that the list of his papers occupies three pages. Those of Sir John Simon also occupy much space. It will perhaps be a surprise to many readers to know what a wealth of MSS the College possesses, and the printing of this catalogue should help to put that wealth at the service of students of surgery, anatomy, and pathology. The title page gives no hint as to whether the catalogue is for sale, or if not, how copies can be obtained.

THE EFFECT OF HIGH TEMPERATURES ON THE MINER

THE atmospheric conditions in hot and deep mines formed the subject of an interesting discussion at the annual meeting of the Institution of Mining Engineers, held in London at the end of October. It arose on a paper by Mr David Peuman, D Sc, principal of the School of Mines at Dhanbad, India, who stated that the Indian collier frequently had to work in a mine with a wet-bulb temperature of 85° F, or even higher. Moreover, the air in most of the working-places in Indian mines is practically still, or at the best very sluggish, yet the miners work day after day uncomplainingly, and not only without mishaps, but apparently without any ill effects. It is well known that persons accustomed to hot damp air are able to work with comfort under hygrometric conditions which would be very trying to men who had not been acclimatized, and Mr Peuman thinks it may be that the acclimatization of the Indian enables him to withstand heat in coal mines better than the average white man. The Indian miner, indeed, prefers to work in a warm place. He likes a gallery in which the temperature is, say, 75° F better than one in which it is 50°. Nor does he like to work in a strong breeze. He wears practically no clothing, whether the mine

atmosphere is warm or cool, thus his whole body is exposed to the drying and cooling action of the air. He also works irregularly, remaining at work for about an hour, and then resting in a cooler place for fifteen minutes or more. While actually at work he is a hard worker, though probably he does not work at a rate equal to that of the British collier. He is, as a rule, shorter in stature and of much lighter build, and consequently expends less energy in physical exertion. But he dislikes any change in the temperature conditions to which he is accustomed, and would resent transfer from a place where the temperature is, say, 88° F and the humidity 98 per cent, to a place where the temperature is 20° lower. Dr J. S. Haldane said that his experience of deep submarine workings off Cornwall, where very high temperatures were registered, was very like that described by Mr Penman, the man in those workings remained there for a short time, and then came out and cooled down, usually under a jet of compressed air. They were exceptionally healthy in spite of the conditions under which they laboured, and did not seem to mind their warm situation. He himself had found it very difficult to remain when the wet-bulb temperature was over 80°, and if the air was perfectly still the limit of endurance was about 88°. A mining engineer from the Rand, Mr James Whitelouse, mentioned that in some of the gold mines there men had to work at a very high temperature, although the ventilation was extremely good. But the African natives appeared to be less happy in the mine than the Indians, perhaps because, though equally inured to hot conditions, they were less accustomed to humidity. A number of them went down with heat apoplexy, these being almost invariably men who had gone straight from their homes into the mine without being acclimatized. It was now a rule on the Rand that the miners should stay for a month in the upper workings, where conditions were less strenuous. Most of the cases of heat apoplexy had proved fatal, until recently a preparation made in Germany, and known as "lobcleine," was introduced, injections of which had been the means of saving a good many lives. Dr Haldane further stated that in his experience of mines in this country he had come across only one case of heat-stroke, this was in a man who was assisting in rescue operations after the disaster at Hamstead colliery. The wet-bulb temperature there was about 85° F, and the man was wearing a flannel shirt. Evidently under the pressure of rescue operations he failed to adjust himself to the temperature conditions—as the white man at least could generally be trusted to do—and died of apoplexy.

"THE CRIPPLE"

We announced a few weeks ago that with the October number the name of *The Cripples' Journal* would be changed to *The Cripple*, and that the scope and aims of the periodical would have a great extension. The October number has lately appeared, and we may say at once that the bold adventure which this change signifies is likely to be fully justified by results if future numbers are as interesting and important as this. When the journal first started its interests seemed mainly to be those of hospitals for cripples and the treatment of deformities, but the new periodical takes not only an international view, but includes practically all that concerns the care and education of cripples and the prevention of deformity in its widest sense as its province. As Mr Watson says in his editorial notes: "It is a vast ambition, because its lines of demarcation are so vague." All the more, therefore, if the new journal is successful, will its achievements be far-reaching. Prevention, treatment, training and rehabilitation—these are the great subjects to be studied and furthered all over the world. Not only is attention to be paid to the unfortunate owners of damaged limbs, to whom the term "cripple"

has usually been restricted, but also those with hearts crippled by rheumatism and with lungs damaged by tuberculosis. As an instance of this extension of the meaning of the term we would cite the very interesting instalment of an article by Dr P. G. Varrier-Jones on village settlements, with a foreword by Sir Robert Jones. The author writes with authority on the subject of the Papworth settlement, which owes so much to his vision and ability. Sir Robert Jones points out the desirability and difficulty of recognizing the onset of tuberculosis in its earliest stages, and the danger of allowing so-called cured or relieved cases of pulmonary disease to return to family life, only to spread infection. Further study and research are necessary before we can hope to arrest tuberculosis in its beginning, but the success of such settlements as Papworth points the way to the prevention of reinfection by returned cases. Sir Robert Jones suggests, indeed, that "the solution of most of the medico-sociological problems of our day will be found in prophylaxis for the fit and village settlements for the unfit." More than half of this first number of the new series consists of an educational supplement, in which is to be found a great deal of interesting and valuable information on education for crippled children and special schools in Britain, and on the position in America, where, since the war, organizations have developed, and are still developing, having for their objects the welfare of cripples in the widest sense of the term. Not only are the various State legislatures engaged in helping charitable organizations, but the Federal Government also helps with money in certain cases. To realize what has to be done it is only necessary to mention that it is estimated that there are 2½ million cripples under 16 to over 1,000 of the population making the shocking total of over 300,000 in the United States.

THE STAGE DOCTOR

A LIGHT HEARTED evening, if not a very instructive one, was provided by the Hunterian Society of London on November 5th, at Cutlers' Hall, when the curtain went up on a discussion on "Doctors and the stage." Two of the promised "stars," Dame Madge Kendall and Dr Harold Dearden, failed to take their parts, but the understudies rose to the occasion. The prologue was spoken by Mr William Devereux, the actor and dramatic author, who confessed that during his forty years on the stage he had played the part of doctors without knowing anything about medicine, his cue was to look preternaturally wise and to affect a bedside manner. Lady Simson (Miss Lena Ashwell) said that she could not remember appearing in a part in which a doctor was represented, and the only play of recent years with any extensive medical interest which she recalled was *The Doctor's Dilemma*, by Mr George Bernard Shaw, of this she had evidently a poor opinion, saying that in its dazzling display of fallacies it matched the most recent work of the same author, *The Intelligent Woman's Guide to Socialism*. Sir St Clair Thomson contributed to the discussion an analysis he had made of the allusions to the profession in the plays of Shakespeare, in which the physician appeared seven times and the surgeon not at all, although the barber-surgeons were a corporate body in Shakespeare's day. Portia, however, bade Shylock "Have by some surgeon," and Lear called for surgeons—"I am cut to the brains." Until he produced *King Lear* in 1606 Shakespeare had rather made fun of the profession, but in that play the doctor emerged as an honourable and sympathetic character, possibly Shakespeare's prospective son-in-law—his daughter was married to Dr Hall of Stratford-on-Avon in 1607—had opened his eyes. In *Pericles* there was to be found as noble a panegyric on the profession as had ever been uttered on the stage. The representation of the profession in contemporary plays was the subject of some amusing

comments by Mr Ivor Back. He remarked on the curious spell which the very name of Harley Street appeared to exercise over playwrights and audiences. Harley Street always seemed to be the only medical thoroughfare worth mentioning. It would be useless to protest that physicians and surgeons had successful practices in Brook Street or Park Crescent, still less in places like Liverpool or Leeds, it must be Harley Street or nothing. The stage Harley Street was immensely long. In the directory it was given only 145 houses, but on the stage the houses went up to a thousand, in a recent play the surgeon lived at 'No. 915.' Moreover, the tenants of Harley Street were nearly all baronets and nearly all surgeons. In the mind of the dramatist Harley Street meant a surgeon's consulting practice and a baronetcy. Why only surgeons? Because the public still thought of surgeons as queer romantic creatures who spent the greater part of their days doing operations of extraordinary gravity, where the deviation of a hair's breadth would inevitably cause the death of the patient. The stage surgeon also had certain characteristics which Mr Back at least had always associated with the physician. He carried a stethoscope and listened to chests, talked a great deal, and administered poisons. In one London theatre at the present moment a play was running in which the surgeon administered poison to his son, doing it in the rather furtive manner in which one would give half a crown to a ducal butler. The stage surgeon, Mr Back continued, was always well dressed but out of fashion. Either he wore a frock coat, or else a cut-away 'morning coat,' when in fact Harley Street had adopted the short black coat and striped trousers of Throgmorton Avenue. The stage version of surgical procedure, too, would hardly be tolerated in real life. Mr Back had seen, on the stage, a thorough examination of the patient take place in the presence of eleven people, including two servants. As for the general practitioner on the stage, he was represented generally as "full of beans, bunkum, and benevolence" occasionally as a buffoon—entering, saying, "Ah, what have we here? A case of double pneumonia!"—or sometimes as a venal scoundrel, in the pay of the villain, administering chloroform to the victims with a handkerchief, and securing, within two seconds, profound anaesthesia with muscular relaxation. Mr Back suggested that in any play of medical interest it might be well to invoke the aid of a medical man to ensure that there were no inconsistencies. This was once done by Sir Henry Irving, who secured the help of two of the most eminent medical men of the time, one a physician and the other a surgeon.

PROGRESS IN BRITISH RADIOLOGY

A YEAR ago the incorporation of the Röntgen Society with the British Institute of Radiology was successfully accomplished, and, commenting on this on October 15th, 1927 (p. 687), we expressed the belief that important contributions to science and practice would follow the happy event. It has been decided by the combined societies to inaugurate the opening of the new session by holding special meetings in London from November 14th to 17th. The proceedings will begin with the delivery by Professor Bragg of the Mackenzie Davidson Memorial Lecture in the Baines Hall of the Royal Society of Medicine on Wednesday, November 14th, at 8.15 p.m. Professor Bragg has taken for his subject x-ray optics, and will illustrate the lecture by experiments. At 10.30 on the following morning an exhibition of x-ray apparatus will be opened at the Central Hall, Westminster, and in the afternoon at 2.30 Mr G. W. C. Kaye, D.Sc., will deliver his presidential address on mediæval and modern radiology, this meeting, in common with the others to be mentioned, will be held at

the Central Hall. At 5 p.m. on the same day the Sirvanus Thompson Memorial Lecture will be given by Mr Sampson Handley, who will deal with radiology from the surgeon's standpoint. At 10 on Friday morning a discussion on the value of the opaque meal in diagnosis will be opened by Sir Thomas Horder, Mr A. J. Walton, and Dr A. E. Barclay, the discussion will be continued in the afternoon. Two other papers will also be read during Friday morning—one on the distribution of x-rays with an irradiated medium, by Mr W. V. Mayneord, M.Sc., and another on some applications of x-ray spectroscopy to industrial problems, by Mr G. Shearer, D.Sc. In the afternoon Mr W. J. Schall will give an address on some engineering lessons from the congress at Stockholm. A dinner will be held at 7.30 that evening at the Trocadero Restaurant, the price of the tickets is 15s (excluding wines), and members may bring friends. On Saturday, November 17th, there will be demonstrations at the National Physical Laboratory of the million-volt generator and the 200 k.v. cathode ray tube. Further particulars of these meetings may be obtained from Dr J. Muir, 32, Welbeck Street, W.1, but communications concerning the dinner should be addressed to Major D. McGrigor, 55, Jermyn Street, S.W.1.

SIR DAVID PRAIN and DR H. H. DALE are recommended by the President and Council of the Royal Society for re-election, on November 30th, as treasurer and secretary respectively of the society. Among the other Fellows recommended for election to the Council are Dr Charles Bolton, Dr C. G. Douglas, Sir Frederick Hopkins, Professor J. C. G. Ledingham, and Professor G. Elliot Smith.

THE next session of the General Medical Council will commence at 2 p.m. on Tuesday, November 27th, when the President, Sir Donald MacAlister, will take the chair and give an address. The Council will continue to sit from day to day until the termination of its business.

GENERAL MEDICAL COUNCIL

ELECTION OF DIRECT REPRESENTATIVES

ASSOCIATION'S CANDIDATES RETURNED

THE result of the voting in the election of two direct representatives for England and Wales to be members of the General Medical Council in the place of the late Dr J. A. McDonald and of Sir Robert Bolam, who has been appointed to represent the University of Durham, was announced on November 1st as follows:

Dr ERNEST KAILE LE FLEMING (Wimborne)	11,455
Dr JOHN WARDLE BONE (Luton)	11,340
Dr Gordon Reginald Ward (Sevenoaks)	4,262
Dr Edward Andrew Gregg (London)	3,108

The constituency numbered 32,758, of whom 15,082 took part. The total number of voting papers issued was 3,579 more than in 1924. Only 368 papers were returned by the Post Office as dead letters, but 720 of the votes received were invalid for one reason or another. Dr Le Fleming and Dr Bone, the two successful candidates, were supported by the British Medical Association in accordance with the decision of the Representative Body at Cardiff last July. On behalf of their fellow members we congratulate them on the result of the election. They will hold office as direct representatives for five years from November 1st, 1928.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

THE BUCKSTON BROWNE ANNUAL DINNER OF FELLOWS
AND MEMBERS

The first annual Buckston Browne dinner of Fellows and Members of the Royal College of Surgeons of England was held on Thursday, November 1st, at the College, Lincoln's Inn Fields, the President, Sir BERKLEY MOYNHAN, Bt., being in the chair. About a hundred guests were present, of whom half were Members of the College, the majority of the others being Fellows. No speeches were made, and the toasts were limited to those of "The King" and

"The Donor." Sir Berkley Moynhan, in proposing the latter, said he hoped that the annual festival now inaugurated would continue to the end of time. To perpetuity there would be two toasts only, and to neither of these would there ever be a reply. The guests were present by the kindness of the donor, and he asked them to drink to the health of Mr G. Buckston Browne.

After dinner the guests were invited to inspect a special exhibition of the original specimens brought back from South America by Charles Darwin, and prepared under the direction of the conservator, Sir Arthur Keith.

The following is a list of those present

Lord Dawson of Penn
Sir Thomas Barlow
Sir George Newman
Sir Alfred Hopkinson
Sir Anthony Bowley
Sir Thomas Holland
Major Leonard Darwin
Sir John Rose Bradford (President R.C.P.)
Mr G. Buckston Browne
Mr G. B. Hillman (Wakefield)
Mr Philip H. Cox
Sir William Bragg
Mr H. M. Hake
Mr O. J. R. Howarth
Mr O. A. Griffiths (Cardiff)
Sir William Lister
Mr J. A. Hayward
Mr H. W. Armstrong
Sir John H. Parsons
Mr J. F. Dolson (Leeds)
Mr W. H. B. Brook (Lincoln)
Mr T. H. Openshaw
Mr Thomas H. Bickerton (Liverpool)
Mr Henry Colgate (Eastbourne)
Mr Raymond Johnson
Sir George Thane
Mr Macleod Learley
Lieut.-Colonel F. E. Fremantle (Hatfield)
Sir Richard H. Luce
Sir Edward J. Pollock
Mr J. F. Jennings
Mr E. F. White (Crowborough)
Dr T. Wilson Parry
Mr H. Bellamy Gardner

Dr G. de Bee Turtle
Dr E. L. Paine
Mr Guy Wood
Mr Richard W. Lloyd
Dr E. M. Callender
Mr Frank Savery
Mr Owen Lancaster
Dr Haden Guest
Mr Ernest Ware
Dr Maurice Newfield
Mr Sidney Spokes (Lewes)
Dr Graham Little
Dr George Parker (Bristol)
Mr E. G. Moon (Broadstairs)
Dr H. B. Brackenbury
Dr Alan Randle
Dr T. W. Shoto
Professor H. E. Roaf
Professor O. Lovatt Evans
Dr G. A. Buckmaster (Bristol)
Dr G. W. Hunt
Dr P. H. Manson Bahr
Dr W. Attlee (Eton)
Dr J. O. Symes (Clifton)
Lieut.-Colonel O. T. Samman (Master of the
Society of Apothecaries)
Dr Walter Broadbent (Brighton)
Dr Astley V. Clarke (Leicester)
Mr Harold H. B. Macleod (Shrewsbury)
Mr J. E. Kilvert (Derby)
Mr G. Francis Smith (Watford)
Dr Hugh Lawson (Chichester)
Dr Gilbert Kumpke (Salisbury)
Dr W. B. Maurice (Marlborough)

Mr Arthur Bostock (Chichester)
Dr Charles Edwards (Andover)
Dr E. Collingwood Andrews
Dr John Gay
Dr E. C. Morland
Mr D. J. G. Watkins (Lincoln)
Mr Philip G. Laver (Chichester)
Sir Alfred Rice Oxley
Mr W. H. Dolamoro

Council
Sir Berkeley Moynhan Bt. President
Mr E. W. Hey Groves Vice-President
Mr V. Warren Low Vice-President
Sir H. J. Waring
Sir Cuthbert Wallace
Mr F. J. Steward
Mr C. H. Fagge
Mr R. P. Rowlands
Mr J. Herbert Fisher
Mr W. Samson Handley
Mr G. E. Gask
Mr W. McAdam Eccles
Sir Charles Gordon Watson
Mr Victor Bonney
Mr Hugh Lett
Mr Leonard P. Camgee
Mr R. G. Hogarth

Mr S. Forrest Cowell (Secretary)
Sir Arthur Keith (Conservator)
Mr R. H. Burne (Physiological Curator)
Mr D. K. Carrels (Assistant Secretary)

LARYNGO RHINOLOGY AND GENERAL MEDICINE

SEMON LECTURE BY PROFESSOR MARKUSZ HAJEK

The Semon Lecture, under the auspices of the University of London, was delivered on November 1st, at the House of the Royal Society of Medicine, by Professor MARKUSZ HAJEK, professor of laryngo-rhinology in the University of Vienna. Mr H. BELL TAWSE, president of the Laryngological Section of the society, presided over a very large gathering.

Professor Hajek, who delivered his lecture in English, said that the invitation to be Semon lecturer filled him with pride and gratitude for two reasons: first, because it afforded him the opportunity of further establishing the relations with his British colleagues which already dated back for thirty-five years, and, secondly, because it enabled him to pay a tribute to the late Sir Felix Semou, who had rendered immortal service to this branch of medicine. Taking for his general theme "Laryngo-rhinology and general medicine," Professor Hajek said that the development of this specialty, in particular the rapid advances in the realm of diagnosis, had, so to speak, intoxicated the first generation of specialists, with the result that the specialty had become detached, and was not connected with general medicine, as it should have been. He gave some illustrations of the unfortunate results which followed over-enthusiasm for a specialty to the disregard of the larger field. He had known a patient treated most admirably for a condition of the larynx, with no regard to the fact that she was suffering from generalized tuberculosis, from which shortly afterwards she died. His verdict on the case was, "The larynx healed, the patient killed."

Laryngo-rhinologists to-day endeavoured, most properly, to complete their clinical observation by resort to the laboratory—by histological and serological examinations, and by the x-ray picture. Every clinician was aware that in a large number of cases it was not possible, from clinical observation alone, to speak with certainty of definite disease. In certain forms the clinical picture was sufficient, but there were intermediate forms which could not be interpreted with absolute certainty, and in such cases

the laboratory diagnosis was apt to be made the deciding point. In the lecturer's view this had led to an over-emphasis of the value of laboratory tests and an under-valuation of the results of clinical experience. He was fearful lest, in the widespread dependence on laboratory methods, what had been achieved by the long practice of clinical medicine should go by the board. Clinicians themselves tended to think that while clinical observation often could not say "Yea" or "Nay," the power of absolute proof did belong to laboratory diagnosis, an assumption which he contested as being by no means correct.

Remarking that the findings of the laboratory were not absolute, but comparative, the lecturer proceeded to give a few examples from his experience, illustrated by microscopical sections, where the histological finding had proved to be misleading. It was forgotten that the so-called histological diagnosis was the product of a series of histological pictures, and that the way in which these separately and collectively were assessed, and held to demonstrate or not to demonstrate a particular condition, reflected the personal view of the histologist. Often these histological pictures confused the clinical findings, yet many specialists still believed in the infallibility of the histological results. He showed three cases in each of which the result of the histological examination was a positive diagnosis of carcinoma of the larynx, yet two of these patients were shown by the after-history to have been free from carcinoma, they had been well now over a long period, and the remaining patient proved to have, not carcinoma, but tuberculosis. He added that histologists were not always agreed among themselves as to what was positive and what was only suspicious, one and the same histological picture was differently interpreted by different histologists. Histological findings as a guide and corrective were of great use in relation to the results of other observations, but they must not be taken as conclusive in themselves, the same remarks applied to the results of serological examination. He pleaded that laryngologists while neglecting no help which might come from this side or that should hold fast to their clinical diagnosis, the principles of which had been laid down with great care and diligence by their predecessors.

As for radiology, the errors following from radiological findings were legion. Radiology itself was not to blame, but the wrongful interpretation of the radiograph and the assumption that the radiological finding was sufficient for diagnosis. Radiology, in order to present its indispensable character in the brightest light, often over-reached itself. The lecturer showed examples of one or two cases in which the precise situation of a foreign body impacted in the air passages had been misinterpreted as a result of reliance upon the x-ray finding solely. He quoted—without his own endorsement, however—one authority in this branch of medicine who had said that radiology in this field had confused more issues than it had clarified. Radiological findings, like the histological and serological, needed to be fitted into the entire series of investigations, but clinical medicine must not be placed in the background. He likened the whole investigation to a symphony orchestra, in which every instrument had its proper place and significance, while the conductor—in other words, the clinician—harmonized the whole. The specialist must be a critic of the laboratory findings and in order to do this he should be familiar with the difference between certain and doubtful laboratory indications.

In considering the general relations of the specialty of laryngology to medicine and surgery as a whole, the lecturer again urged the need for a comprehensive view. The separate findings of the specialist were not sufficient, and regard must be paid to the entire clinical picture. The importance of this specialty to general medicine was self-evident. Only too often the first sign of a general infection or disease was manifested in this region. With regard to surgery, the first generation of laryngologists took too narrow a view, only with difficulty had the new generation gradually learned its way in surgical method. To-day surgical training was a *sine qua non* for the laryngologist. Young physicians should not dedicate themselves to laryngology immediately or soon after the completion of their studies, particularly if they intended to become teachers. They must first have a good general grounding in all the principal departments of medicine, only then could they develop their specialty scientifically. The house was not built from the gables to the foundations, but the reverse, and, to change the figure, laryngologists would do well to cultivate the field of general medicine in order that their own special fruit might be brought to its finest.

SIR STCLAIR THOMSON, in proposing a vote of thanks to Professor Hajek, mentioned that among previous Semon lecturers had been savants from Berlin and Paris, and now the great school of Vienna had made its contribution. Professor Hajek was a pioneer who differed from most pioneers in his intense conservatism, which he had exemplified in the lecture. SIR JAMES DUNDAS GRANT seconded the vote of thanks, which was heartily carried, and Professor Hajek was then presented with the Semon plaque.

India.

Women's Hospitals in the Central Provinces

A CONSIDERABLE advance in the provision of medical treatment for women by members of their own sex has been made in the Central Provinces and Berar in the course of the past year. Colonel J. Norman Walker, inspector-general of civil hospitals, in his notes on hospitals and dispensaries in 1927, reports that two special women's hospitals were constructed during the year, both of which are now in operation, while women assistant surgeons have been attached to main hospitals in seven centres where no special women's hospital exists. Provision for five more assistant surgeons has been made in the budget for 1928-29. In addition to the women assistant surgeons there are nine women assistant medical officers attached to certain dispensaries, and the number is being increased by two. Regarding the general question of the provision of medical assistance, Colonel Walker states that the budget for 1928-29 provides for opening additional cheap plan dispensaries in certain areas. The policy of the Government

is to leave the initiative to local bodies, with the assurance that proposals for the establishment of dispensaries will receive sympathetic consideration and financial assistance. The demand has been noticeably better from Berar than from the Central Provinces. Government approval has been given to a scheme for subsidizing qualified private practitioners who agree to settle in villages distant not less than eight miles from existing dispensaries, but no funds were available for this service in 1927, although it is expected that some progress will be made with the scheme in the current year. An official investigation is being made into the question of grants to local bodies and dispensary committees for the maintenance of hospitals. Colonel Walker holds that "when one considers that the voluntary system has failed, the ticket system has failed, and that other provinces have given up the ticket system, it is difficult to see how these public institutions can be adequately supported without more generous support from provincial or local revenues." He sees no reason to believe that, should the Government allotments be generously increased, voluntary subscriptions from the philanthropic would be reduced.

Burma Government Medical School

The Burma Government Medical School commenced the session 1927-28 with seventy-nine students on the register, but as an earlier order for the closing of the school was still in force, no new students were then admitted. This order had been made in pursuance of the policy of the Government gradually to replace the class of sub-assistant surgeons by the more highly qualified licentiates in medicine and surgery, and to the effects of this decision the superintendent of the school Lieut.-Colonel T. F. Owens, I.M.S., attributes a deterioration in the tone of the establishment and the high percentage of failures recorded in his report. In the course of the session, however, the Government decided to reopen the school, and thirty-eight new students were admitted to the four years' course which it provides. From the report it appears that the school buildings are in urgent need of reconstruction or replacement now that the institution has been re-established. The report of the inspector-general of civil hospitals in Burma, Colonel W. H. C. Forster, states that fifty-six students were under training in 1927 for the degree of M.B., B.S., and sixteen for the diploma L.M. and S., in addition to the 117 already noted as attending the Government Medical School. Regarding the class of sub-assistant surgeons employed in the services under his control Colonel Forster mentions that the number on the rolls decreased during the year from 436 to 427, and that the shortage was so acute that all leave had to be stopped. An increase in the cadre to a total of 475 has been requested. It may be added that this class is by far the most numerous in the Burma medical service, the total number of officers sanctioned in other and superior classes being about 150.

Blindness in Sind

The annual report of the Thakurkarkar (Sind) branch of the Blind Relief Association for 1927-28 suggests that the census reports relating to blindness in India under-estimate considerably the incidence of this disability. It is recalled that the census figures for India and for the Bombay Presidency give the incidence of the total blindness as 14 per 10,000 of the population, generally, the report states, the figures are two or three times too low. In a count by an official in the United Provinces over 90 totally blind per 10,000 were found, and in the part of Sind from which the report emanates the figure is at least 40 per 10,000. The association seeks to overcome the difficulties created by ignorance, apathy, and lack of medical facilities which prevent the treatment of many cases of blindness susceptible to curative surgical measures, it also undertakes preventive work. In this task the main problem has been to obtain capable and suitable medical officers for touring work in the districts. There appears to have been a substantial reduction in the number of cases requiring operation in the area in which the association has been carrying on its campaign during the past three years, and it has therefore been possible to extend its activities to cover the greater part of Eastern Sind. Mr. Saheanand, the association's medical officer, dealt with about 10,000

cases, including over 2,000 in which major operations were performed, at camps in various districts. In Upper Sind, at Shirkapur, Dr Holland of Quetta spent some six or seven weeks in work among the blind with the assistance of surgeons from Europe and America, nearly 3,000 cataract and other operations were performed. Although this work has been continued for a considerable period, thousands of cases are still in need of attention.

Hospital Provision in Assam

Several important schemes for improving the hospital facilities of the province of Assam are in progress, and a substantial improvement in this direction should be shown in the course of the next few years. In his report for 1927 Colonel G. Hutcheson, inspector-general of civil hospitals, states that schemes are under consideration for the construction of two new hospitals for men and women at Sylhet, and of a new civil hospital at Shillong, while a project for a new civil hospital at Sadiya has been forwarded to the Government of India for approval. At present there are no women's hospitals in the province, and the arrangements for labour cases and the treatment of diseases of women are inadequate. The new women's hospital at Sylhet will be the first of its kind. Colonel Hutcheson suggests that such hospitals should gradually be provided at all important district headquarters. He also calls attention to the deficiency of provision for the well-to-do class of private patients, or for Government servants, who can afford to pay for their accommodation; it is proposed to provide blocks of private wards for orthodox Indian men and their families, and also for those who live in European style, in the new civil hospital at Shillong. The attention of local boards is directed to the need for considering the question of constructing private paying wards in connexion with their more important dispensaries. In the course of the year work on the new medical school at Sylhet was commenced, and its completion is expected to take about two years. A substantial increase in the number of patients at the State public, local fund, and private aided hospitals and dispensaries was again recorded, the total being 1,620,012, against 1,559,001 in 1926 and 1,471,239 in 1925, the number of in-patients rose from 11,812 in 1926 to 12,369 last year, and the number of out-patients from 1,547,189 to 1,607,643. Cholera was much more prevalent in 1927, when 5,013 cases were treated, against 1,845 in the previous year, in the Sylhet district alone 2,167 cases occurred. The decline in the incidence of, and mortality from, kala-azar, to which reference was made in the *Journal* of February 18th (p. 283), continues, last year 8,277 cases were treated and 88 deaths recorded, this compares with 10,416 cases, with 134 deaths, in 1926 and 15,823 cases in 1925.

Scotland.

Scottish Department of Health Chief Medical Officer

The Secretary of State for Scotland has appointed Dr John Parlman Kinloch to be Chief Medical Officer in the Department of Health for Scotland, which on January 1st next will take over the powers and duties of the Scottish Board of Health. Dr Kinloch, who is 43 years old, graduated at the University of Glasgow in 1909. At present he is medical officer of health for Aberdeen and head of the Public Health Department of the University of Aberdeen.

Grenfell of Labrador Rector of St Andrews

Sir Wilfred Thomason Grenfell, best known as "Grenfell of Labrador," was on November 3rd elected Lord Rector of St Andrews University by the undergraduate members, defeating his opponent, Lord Melchett, by 157 votes. The candidates, as is customary at St Andrews, were selected on non-political grounds—Sir Wilfred Grenfell being chosen for his distinguished services to humanity and medical science, and Lord Melchett for his part in the promotion of industrial peace. Sir Wilfred Grenfell succeeds to an office vacated by Dr Fridtjof Nansen and held previously

by Sir James Barrie and Mr Rudyard Kipling. In July last year, it may be recalled, the King conferred the KCMG upon him in recognition of his thirty-five years' work as a medical missionary in Newfoundland and on the Labrador coast. He was born in 1865 and received his medical education at Oxford and the London Hospital, obtaining the diplomas LRCP, MRCS in 1888, and being elected FRCS in 1920. He was made CMG in 1906, and has received honorary degrees from Oxford, Harvard, and Toronto.

Pollomyelitis in Glasgow

The usual sparse incidence of poliomyelitis in Glasgow was maintained until the end of June, but since the beginning of July there has been a very definite increase in the number of cases, from July 7th to October 20th eighty-six cases were reported, and in the four four-weekly periods contained within these dates the number of cases sickening was fifteen, nineteen, twenty-seven, and twenty-five respectively. The disease was distributed generally throughout the city, and there was only one instance in which two definite cases occurred in the same household. Various instances of the occurrence of febrile illnesses, presumably the so-called abortive attacks, were, however, reported among members of a family round about the date on which a declared case sickened. A definite grouping of cases occurred in connexion with a day school, four pupils of the infant classes and two of the junior classes being affected, the first three cases were in the infant classes, and these sickened in the same week. The disease attacked all classes of the population. Approximately 63 per cent of the population of Glasgow live in houses of one and two apartments, and 66 per cent of the cases occurred in these. Clinically the disease has presented no unusual features. At the onset the majority of cases showed vomiting and feverishness, but cases of the sore throat type of onset were not uncommon. The deaths among the eighty-six declared cases occurring between July 7th and October 20th numbered seven, giving a case mortality of 8.2 per cent. Cases of the disease have come under notice also in other parts of Scotland. During the thirteen weeks ended September 29th, fifty-four cases, including thirty in Glasgow, were notified in the sixteen principal towns, and the counties of Lanark and Fife, compared with the lower figures of twenty-two and seven in the corresponding periods of 1927 and 1926 respectively. The Scottish Board of Health, on October 22nd, circularized medical officers of health, suggesting that they should keep a close watch on their areas and that they might ask practitioners to bring to their notice any suspicious case.

Sunlight and Health

A public lecture on the influence of sunlight on health was given in Edinburgh on October 31st by Lieut-Colonel J. de P. Langrishe, DSO, lecturer on public health in Edinburgh University, who referred to the value which was placed by the Greeks and Romans upon sun culture, and to the special "solaria" or sunning places on their houses, saying that in the care of the health among these peoples sunlight was of the greatest importance. Air, light, and gymnastic exercises, he continued, were the foundations for physical and mental health, and the sources of strength. The stimulating effects of sunlight on our feelings of comfort and happiness were particularly obvious in the constant changes of weather observable in the cloudy British climate, this climate would be ideal if there was more winter sun with bright frost and snow. The lecturer described the composition of sunlight as containing a huge range of electro-magnetic rays, with wireless rays at one end of the spectrum and the extremely short ultra-violet rays and still shorter gamma rays and heat rays at the other end. The defective powers of penetration possessed by rays of short wave-length explained why ultra-violet rays were obstructed by dull skies, smoky atmospheres, crowded buildings, and even by thick clothing. This obstruction of sunlight not only affected human beings directly, but extended to plant life, so that vitamins were produced in defective quantities in vegetables and fruits. Pollution of city atmospheres by smoke—one of the most serious

causes of light obstruction—was being successfully attacked in various places, and could ultimately be removed by a strong public opinion. In Pittsburgh smoke pollution had been reduced by 85 per cent, and certain German industrial towns were now smokeless. Domestic fires were largely to blame for smoke pollution, and the wider use of gas electricity, and coke in the home should be secured. In summer much could be done by a greater amount of sea bathing with suitable precautions, the early morning sunlight was richest in ultra-violet rays. In conclusion the lecturer urged the importance of eating fresh foods, particularly dairy produce and fruits which were in effect "bottled sunshine."

Research in Animal Breeding

Mr A D Buchanan Smith, of the Animal Breeding Research Department of the University of Edinburgh, in the course of an address on recent advances in animal breeding research at Perth on November 2nd said that science consisted much in the making of careful observations and the accurate record of them so that when sufficient experiences had been collected some law could bring the various pieces of information together, and thus the scientist could be enabled to look ahead, plan experiments, and define the law more precisely. The science of animal breeding was still very young, having been born in the present century, and its exponent were learners, rather than teachers, who were always glad of advice from those who had had great experience. The most important work being done at Edinburgh and elsewhere was in regard to the inheritance of economic characters of livestock, such as good conformation in meat-producing animals or milk production in dairy cattle. Considerable time was being devoted to finding out what type of pig was most suitable for the Scottish bacon market from the producer's point of view. Research was also being conducted into the subject of inbreeding and into that of sterility, which constituted one of the greatest menaces of the stock-breeding industry at the present day. The breeder should always be careful to include fertility in his idea of a perfect beast. With regard to the question of resistance to disease, breeders had known from time immemorial that some animals were harder than others and that hardiness was inherited, but it had been shown only within the past few years that certain individuals possessed resistance to definite diseases, and that these specific resistances were also inherited. The main object of this new science was not to see what could be produced to-day or to-morrow, but what information could be brought together and arranged in an orderly fashion so that it could be understood and applied in the future.

Fifty Years' Service as a Lecturer

Dr Thomas William Drinkwater who has completed fifty years of service as a lecturer in the School of Medicine of the Royal Colleges of Physicians and Surgeons at Edinburgh, was entertained on November 1st at a dinner in the Hall of the Royal College of Surgeons. Sir David Wallace, who presided over a company which included some forty of his fellow lecturers and colleagues in the School of Medicine, remarked that they were met to do honour to Dr Drinkwater, as it was a unique event that a lecturer should have continued to hold classes throughout the long period of fifty years, Dr Drinkwater having been appointed a lecturer at the commencement of the winter session of the year 1878. Dr Drinkwater, after completing his medical studies at St Thomas's Hospital, London, and at Edinburgh, qualified in this year, and almost immediately commenced lecturing on chemistry. In addition to conducting large classes, he was one of the earliest chemists to commence analytical work in connexion with the public health movement of last century. He had been public analyst to various burghs, such as Fortrose, Inverness, and Forres, and public agricultural analyst to the county of Ross and Cromarty. For a time he was assistant to the professor of forensic medicine, in the department of toxicology at the University of Edinburgh, and examiner in chemistry to the Royal Agricultural Society of London. He had made numerous literary contributions, both to the

teaching of the subject and to analytical work. For many years he was a well-known figure at students' entertainments, and his great abilities as a pianist, a reader of humorous songs, and a raconteur were in much demand. Despite his long tenure of office, Dr Drinkwater is still actively engaged in teaching and in chemical analysis for medico-legal work.

Longmore Hospital for Incurables, Edinburgh

The annual meeting of the Royal Edinburgh Hospital for Incurables (Longmore Hospital) was held on October 26th. Mr J J Herdman, chairman of the board, who presided, stated that the number of patients under treatment was 337. He said it was a tragic fact that out of 247 applications for admission only 128 could be accepted, and that many of the applicants died before accommodation could be found for them. On the list of applicants there was always a considerable percentage of severe cancer cases, and the managers had under consideration a scheme whereby, through rearrangement of the wards, additional accommodation could be found for women, who constituted the greater number of applicants. Dealing with the accounts, the chairman said there was an increase of over £500 on the ordinary income compared with last year, but an increase of £762 on the ordinary expenditure. The managers deplored the very heavy drain upon capital income which was required to meet the deficiency in ordinary income, for this year they had drawn upon extra ordinary income to the extent of about £8,000. An outstanding need was for a very definite increase in the amount received from annual subscriptions. Professor John Fraser, in seconding the motion for adoption of the report, said that one of the deepest shadows on human life was that of the disease or accident which either snuffed the vital spark from day to day or left the sufferer living but helpless. This hospital provided a resting-place for such persons, and the patients gave an impression of a sense of happiness which might fill them with wonder. In several instances, too, children who had been thought crippled beyond repair had regained in the hospital the full power of their limbs, and such experiences made them appreciate the splendid care and attention which the sufferers received.

Gifts to Scottish Universities for Bacteriological Work

Among benefactions reported at a meeting of the Court of the University of Glasgow on October 31st, was a gift of £10,000 from Mr William C Teacher of Cove, for the foundation of a lectureship in bacteriology at the Royal Infirmary, Glasgow. At a meeting of the Edinburgh University Court, held two days earlier, intimation was received of a gift of £5,000 from Sir Leybourne Davidson of Huntly Lodge. This sum is to be utilized for the foundation and endowment of a fellowship for the encouragement and promotion of research in bacteriology and immunology.

Dramatic Production in Aid of a Medical Charity

The Albany Players, a well-known Glasgow amateur dramatic company, will, on Wednesday, November 21st, and the three following evenings, give four performances in aid of the Glasgow branch of the Royal Medical Benevolent Fund Guild. At these performances, to be given in the Athenaeum Theatre at 7.30 p.m. each evening, the company will present a light comedy, "Healing Waters," which has a strong medical interest and contains a good flavouring of Scottish humour; it is in part a skit on the novelists of the "kailyard" school, and treats with gentle satire those who seek "cures" at the "Healing Waters." The author, Dr John Fergus, is a well-known figure in Glasgow literary circles as a writer of verse in the vernacular, among his most popular poems being "The Kirk" and "The Old Parish Doctor." Among the leading members of the company is another Glasgow medical practitioner. Vouchers may be obtained from Mrs Fergus, 1, Parkgrove Terrace, Glasgow, C 3 and others, and from Messrs J D Cuthbertson and Co, 226, Sandhurbill Street, where seats may be booked.

England and Wales.

Iris Fox Memorial

A FUND has been raised to erect a permanent memorial to the late Dr C Iris Fox, who died in January, 1926, from septicaemia contracted during a *post-mortem* examination at the Royal Free Hospital, where she was senior assistant pathologist. A sum of £345 has been collected, and it is proposed to devote the money to the provision of a pathological library at this hospital to be named the "Iris Fox Library," a commemorative medallion or plaque being placed inside the room. Plans for the extension of the pathological department of the Royal Free Hospital have been prepared, though it may be some time before actual building can begin. Should it be found impossible eventually to allow space for a library, one of the new research laboratories would be similarly endowed to her memory.

University of London Medical Graduates' Society

The autumn dinner of the University of London Medical Graduates' Society was held at the Langham Hotel, Portland Place, on October 31st, with the president, Sir StClair Thomson, in the chair. Dr M Hajek, professor of laryngorhinology in the University of Vienna, and Dr Waldapfel, his assistant, were the guests of honour, and among others present were Sir Charlton Briscoe, Bt, Lady Briscoe, Mr Herbert Tilley, Dr Wilfrid Edgecombe, Mr T P Legg, and Sir Holburt Waring, formerly vice-chancellor of the University. The president, after calling attention to the progress of the society, said that it was hoped to bring in a large proportion of the 4,500 medical graduates of the University in the course of time, and thus to intensify corporate feeling. Sir StClair Thomson spoke of his previous study under Professor Hajek more than thirty years previously; the professor had now received the long overdue recognition which his past services to laryngorhinology deserved. In replying, Professor Hajek expressed the great pleasure he felt at being so honoured in England. Mr W McAdam Eccles later referred to the success the society had achieved in the Birmingham area through the initiative of Professor Billington, he mentioned that its first extra-metropolitan dinner would be held there on November 23rd. Describing the progress of developments in connexion with the Bloomsbury site for the University, Sir Holburt Waring stated that eleven acres had been acquired for £535,000, the necessary legal powers had been secured, and they were now able to go ahead with the scheme. The authorities were considering what colleges, institutions, and special departments should be erected there, and when this had been decided plans for the whole area would be prepared.

Maudsley Hospital, Denmark Hill

A course of instruction for the diploma in psychological medicine will be given at the Maudsley Hospital during the next five months of next year, commencing on January 28th. As in previous years the course will consist of two parts, of which the first will extend over January and February and the second will follow in March, April, and May. The first part includes a series of lectures on the physiology of the nervous system, by Dr F Golla, who will also give demonstrations on physiological psychology; these will be supplemented by a short theoretical and practical course on the biochemical aspects of mental disorders, including laboratory methods. Twelve lectures on the anatomy of the nervous system will be given by Professor G Elliot Smith, with practical instruction by Mr F Geary, and lectures and demonstrations on theoretical and practical psychology by Dr Henry Devine. The work of the first part of the course will commence, generally, at 2.30 p.m. daily. In addition to the foregoing four lectures on psychological mechanisms will be delivered by Dr Edward Mapother, on Fridays February 22nd, and March 1st, at 2.30 p.m. and 4 p.m. In the second part of the course, from March to May inclusive, Dr Mapother will give lectures on morbid psychology and demonstrations in clinical psychiatry, Dr Bernard Hart will lecture

on the psychoneuroses, Drs Golla and F M R Walsh will give instruction in clinical neurology, and the former, with Mr Charles Geary, will deal with the pathology of mental diseases. Lectures on the legal aspects of insanity will be given by Dr C Hubert Bond, on mental deficiency by Dr F C Shrubbsall, on crime and insanity by Dr W Norwood East, on therapeutics by Dr A A W Petrie, and on abnormalities of the fundus oculi by Mr R Foster Moore. Mr S A Mann will give demonstrations of laboratory methods. Voluntary clinical assistantships are available at the Maudsley Hospital without fee to practitioners of either sex specializing in psychological medicine; they can be held in conjunction with attendance at either part of the course. These appointments satisfy the requirements of the various examining bodies in respect of clinical experience for the diploma in psychological medicine or for the M.D. in psychological medicine. There are also various other opportunities for clinical study, also without fee, open to all attending the course, fuller information may be had from the medical superintendent of the hospital. Inquiries about the lectures should be addressed to the Director of the Central Pathological Laboratory, Maudsley Hospital, Denmark Hill, S.E. 5.

Correspondence.

SCHIZOPHRENIA (DEMENTIA PRÆCOX)

SIR,—Many of your readers will be aware that the accommodation of institutions for persons of unsound mind is to a large extent taken up by patients who illustrate the above-named disorder, mainly in its chronic, irrecoverable stages. For many psychiatrists—probably the majority—the problem of the pathogenesis of the conditions commonly grouped under the designation "schizophrenia" is the most urgent they have to deal with. In so far as there are differences between the symptoms and course of schizophrenia on the one hand and epidemic encephalitis on the other, my view is that such are explicable on the basis of difference in the irritability in the two cases, in the inherent mode of reaction. As regards the irritants, it is a matter for investigation whether that is the same or not.

It rejoices me to believe that the great majority of your readers are mercifully absolved from the duty of perusing British and foreign journals of psychiatry. But others, like myself, who (I hasten to assure you, through no fault of their own) have been condemned to study such must have observed that sometimes and lately there has passed a glimmer of suggestion, there has even been seen the steadier glow of evidence athwart this murky literature, going to show that some in different lands are pondering the relationship between the two conditions referred to.

Epidemic encephalitis is placed amongst the "virus diseases," amongst those pathological conditions which, with greater or less justification, are ascribable to filterable viruses. The early schizophrenias of psychiatry and the encephalitics of general medicine should I think, be investigated together—on the same lines. The doctrinaires, of course, are always with us, prepared to demonstrate, on paper, that these conditions are fundamentally different. They cannot be allowed to numb and bring to naught the initiative of investigators. We are sick of disputation, disquisition, and differentiation in this matter of schizophrenia. The perpetrators of such have occupied the stage too long. I would fain see the safety curtain lowered upon them, and kept *in situ* until the boss behind had done its work. What we require in respect of psychiatry in general, and schizophrenia in particular, are silence and skilled research. Our problem is how to get hold of the patients concerned in the earliest stages possible, and to bring them in touch with centres where the necessary research can be done. Obviously the psychiatric clinic in working association with the general hospital is what is needed. Such clinics, as you are aware (with the exception of the Maudsley Hospital) are not yet available in England and Wales, since legislation has not been introduced to facilitate investigation and early treatment of the psychoses. Deplorable and humiliating as this position is, I can say

from my practical experience that the necessary research can be carried on, to a limited extent, in the meantime, in the following manner

A mental hospital near to, and in close working association with, an adequately staffed general infirmary is equipped with the necessary staff and laboratory facilities and authority to conduct animal experimentation. It has amongst its visiting medical men members of the infirmary staff competent in different branches of medicine. Very rarely in an early case of schizophrenia is received direct, but when, as should be the case, an out-patient clinic in psychiatry is conducted at the infirmary by one of the staff of the mental hospital, instances of the disorder in an early phase are from time to time available. The necessary apparatus for collecting material is kept at the pathological laboratory of the infirmary as well as at the mental hospital. The case is watched at the infirmary, by the kind co-operation of the physicians, the material for investigation is removed at the infirmary and forthwith transferred to the mental hospital, there to be dealt with by way of cultivation, animal inoculation, etc.—I am, etc.,

Cardiff City Mental Hospital Nov 1st

LUDWIG GOODALL

HYPOCHONDRIA

SIR,—Dr Gillespie's paper and the discussion on this subject reported last week (p. 795) touch on a number of interesting points. I am surprised that no reference was made (except in a casual way) to the vascular factor. I think most physicians will agree that a very high percentage of cases have some circulatory disturbance—they are either profound vagotonic or well-marked arteriosclerotics. If this is the case what is the explanation?

It seems to me that Dr Gillespie has somewhat confused the issue as regards hypochondria and hysteria. From the therapeutic point of view the difference is clear enough: the hysteric improves with isolation, because his symptoms depend on his relations to the outside world; the hypochondriac is relatively unaffected because his misery is subjective and generated within. Jung's type-psychology is helpful on this point.

Again, the anxiety factor offers a fairly clear-cut line of demarcation. Hypochondria, as I understand the term, is not applicable to cases in which somatic preoccupation coexists with generalized anxiety. If a man is as much worried about his stocks as about his stomach he is an anxiety case and not a true hypochondriac.

It seems to me impossible to consider hypochondria usefully apart from the basic conception of self-love (the Freudian narcissism) and its transmutation to obsessional self-pity. This conception offers a clue to the onset of the symptoms. The expression of self-love has generally been the keynote to all the hypochondriac's life. External circumstances turn that emotion inwards and it takes the form of stereotyped self-pity.—I am, etc.,

London W 1 Nov 5th

H. CRICHTON-MILLER

PAY BEDS IN VOLUNTARY HOSPITALS

SIR,—The report of the Special Committee of King Edward's Hospital Fund for London on the subject of pay beds at voluntary hospitals, while recommending a large increase in the number of such beds, contained also the following paragraph:

We doubt whether the nature and extent of the existing pay bed accommodation at voluntary hospitals is generally known by the members of the middle and professional classes. We suggest that the Management Committee of the King's Fund might consider whether the Fund should prepare and publish year by year for the information of the public a list of the pay beds at the London voluntary hospitals, with rates of charge and other particulars.

The report itself, which can be purchased for 1s 5d, post free, contains in an appendix particulars of all the pay beds now available in the King's Fund area, and also a list geographically arranged. The Management Committee are at present considering the recommendation quoted above, and would be glad to receive any information on the question whether a similar list, if prepared

and issued annually, would be likely to be of use to the public and to the medical profession throughout the country.—I am, etc.,

SOMERLEYTON,
Honorary Secretary and Vice-Chairman
of Management Committee

London, Nov 5th

HOSPITAL POLICY

SIR,—I attended a meeting of the medical staffs of our county hospitals a few days ago, and should like to give your readers my impressions of the meeting.

The two larger hospitals are both anxious to adopt the B.M.A. policy, and get a percentage paid to the medical staff funds for tariff patients. The other hospitals are all anxious to help these hospitals, and most of them voted for the Association's policy with that idea, but, with one exception, none of them intend to carry that policy into force in their area. The reason is that what suits the large hospitals does not suit them. Of course, I think that the staffs of the large hospitals will rue the day when they lose their status as free men, and the younger men will not bless them for doing it. But that is neither here nor there, what is important is the position the small hospitals are being placed in.

In a small town, at any rate, if the medical profession cares to see to it, it is quite possible to prevent abuse of a contributory scheme. The contributory scheme in itself surely should be welcomed if it is designed as a contribution towards the upkeep of a voluntary hospital. Where a scheme has no contract, and where a payment is asked for as a contribution and not demanded as a right, payment for maintenance should be encouraged. If the workers pay 1d or 2d a week, with full knowledge of what they are doing—as they will do—then they should be thanked for doing so. Abuse arises when these boundaries are not understood and insisted upon. No difficulty arises where a patient is admitted because of the urgency of his case and on the recommendation of the doctor, and it is understood that his contribution is only for maintenance in the hospital. The position of the medical staff is then one of honourable independence, and the staff can use this for the benefit of the voluntary hospital.

In order to define the position of the medical staff and create a foundation from which action can be taken later on if necessary, I should like to see a resolution such as the following passed by all hospital boards and made clear to all contributing authorities:

"That contributions are for maintenance only, and the medical staff reserve the right to be paid for attendance in suitable cases after the full cost of maintenance has been met."

I submit that this would clear the air, and is something that everyone can understand.—I am, etc.,

Leitchworth Oct 29th

NOAH MACFADYEN

X-RAY DIAGNOSIS

SIR,—If Mr Gilbert Scott will refer to the dictionary he will find a fallacy described as "an argument which professes to be decisive of the matter at issue, while in reality it is not." It is in this sense that I use the word "fallacy," and I know that many surgeons will agree with me that the present position of radiography in abdominal diagnosis justifies my choice of a title.

There is another definition of "fallacy"—"a deceptive appearance"—which is equally applicable as the word "mistakes," which Mr Scott prefers. "The fallacy of x rays" is due to the many pitfalls which lie in wait even for the experienced radiologist. There is an old adage, "If you have a bad case, abuse your opponent." Both Dr Heinemann-Johnson and Mr Scott suggest that the "mistakes" to which I refer are due to the inexperience of the radiologist. The "mistakes" are the considered opinions not of one, but of several of the most expert radiologists in London, for whose work I have the greatest admiration, but who are not young enough to be infallible. They will be both surprised and gratified to learn that they are guilty of "gross mistakes and lack of judgement."

Dr Whorlow takes me to task for condemning house-surgeons for sending cases for a radiological report before

making a diagnosis, and asks me, "Why?" Such house-surgeons and students in hospitals are there to learn their jobs? How are they to acquire skill to diagnose fractures, when x-rays are not available, if they do not train their hands as well as their eyes and ears during their apprenticeship? I trust Dr Whorlow will not have the misfortune to fracture a leg, as I am confident he would not enjoy the journey to the radiologist, or even to a radiological couch, without first allowing the surgeon to "lay hands on him." His knowledge of surgeons must be either unfortunate or scanty if he imagines that a fractured limb cannot be examined without causing pain.

Why Dr Whorlow thinks I am unduly impressed with the radiogram I cannot imagine. Nothing in my paper suggests such an idea. On the contrary, the fact that I emphasized the importance of the presence of the surgeon at the radiological examination negatives such an assumption. Dr Whorlow must be congratulated on his ability to demonstrate 98 per cent of gastric ulcers by means of barium meal examination. I have never previously heard of any radiologist who could attain such a degree of accuracy. Indeed, I do not think any surgeon would claim to be able to discover 98 per cent of gastric ulcers even after opening the abdomen.

It would encroach too greatly on your space to answer in detail all the criticisms in Dr Whorlow's letter. The gist of it is that a radiologist should not make mistakes, and, therefore, the radiologists who make them are incompetent. Probably the radiologists whose help I have enjoyed would disagree with Dr Whorlow. They might even suggest that it is he who is mistaken. Therefore the logical conclusion to be drawn from these opposing views is that all radiologists are incompetent, a view with which, I need hardly say, I would totally disagree. On the contrary, seeing that radiography is simply an interpretation of shadows, the wonder is that mistakes are not far commoner. It is easy to be wise after the event. May I suggest to Dr Whorlow that it is noiser difficult to interpret the x-ray findings in the light of what has been found at operation, but very difficult, and often impossible, to determine beforehand the conditions which will be revealed on the operation table?

My paper was intended, not to depreciate the value of radiography when used with judgement and discretion, but as a protest against a growing tendency to regard a radiological report as gospel. I venture to think that the letters of your correspondents fully justify the need for such a warning at the present time—I am, etc.,

London W 1, Nov 5th

HERBERT J PATERSON

SIR,—Is it not time we dropped such futile discussions as that opened by Mr Herbert Paterson at Cardiff, especially when they are based upon the assumption that there is a disagreement between clinicians and radiologists as to the "infallibility" of their respective methods of examination? In a practice of over twenty years as a radiologist I have never had any such difficulty with the physicians and surgeons with whom I have been associated, for the simple reason that they and I have had the sense to realize that there are cases (1) in which the x-ray evidence is necessarily inconclusive, though perhaps of great value when considered in conjunction with the clinical data, and (2) others in which, despite Mr Paterson's emphatic denial, the radiological diagnosis does exist and is final, no matter to what extent the clinical evidence fails to tally with it. As an example of the latter class, I need only cite the screen diagnosis of hydro-pneumothorax, in which the evidence afforded by the shadow of free fluid splashing about at the bottom of a brilliantly translucent air space is so "diagnostic" that I fail to see how even Mr Paterson could deny its "infallibility." Equally positive diagnoses are obtainable in urological and other abdominal examinations by up-to-date methods.

It is quite true, as Mr Paterson says, that the x-ray evidence has to be "read in the light of past experience, and that there is ample scope for error in the interpretation thereof." But why should radiology be singled out for such criticism? Are not the clinical observations of the surgeon also to be read in the light of past experience,

and is there not ample scope for error in his interpretation thereof? Many radiologists have aet with surgical "fallacies" in the diagnosis of dislocated shoulder, for instance. Yet in these cases a radiograph taken by (and interpreted by) a competent radiologist would have given him an absolutely infallible diagnosis, unassisted by any clinical signs or symptoms. In more than one such case it would also have saved the surgeon from having to pay heavy damages.

It is true that Mr Paterson concludes by holding out one crumb of comfort to us poor radiologists, when he magnanimously acknowledges that radiography is "of value." But I affirm that he has said nothing to justify such statements as that the "assumption that there is such a thing as a radiological diagnosis is a fallacy," or that "a radiological diagnosis, as such, does not exist." Such sweeping assertions do nothing to help the progress of medical science, and a little common sense on both sides would do away with the excuse for such discussions as that opened by Mr Paterson at Cardiff—I am, etc.,

Manchester, Oct 31st

W J S BYTHELL

PAEDIATRICS OR PEDIATRICS

SIR,—In your issue of to-day there is amongst the notices of the week a mention of the FitzPatrick Lectures, which are stated to be "On the history of Pediatrics." There is some mistake. I feel bound in all modesty to disclaim any knowledge of this subject.

If it deals with the science of plane surfaces (*παιδια*), I never had any skill in geometry, and am incompetent to deal with it. If, on the other hand, it refers to eursmanship (*παιδος*), or any other form of athletics, such as jumping, I cannot claim to have studied it. Some illiterate person has suggested that the term "pediatrics" refers to boots and bunsions, but I apprehend that the correct term for this would be "podiatrics."

My lectures are concerned merely with paediatrics—the study of children (*παιδες* or *παιδια*)—I am, etc.,

London W Nov 3rd

GEO F STILL

** We respect Dr Still's desire to keep medical orthography on sound lines, but since pedagogy and pedantic (also derived from *παις*) are so split nowadays in good circles, why not pediatrics too? The *New English Dictionary* gives both spellings—pediatrics and paediatrics. A ruling by the Society for Pure English would be welcome, also on two other words in common medical use—*orthopaedics* or *orthopedics*, and *aetiology* or *etiology*.

THE DURATION OF PREGNANCY

SIR,—Recent publications have, I think, awakened a renewed interest in the factors determining the period of human pregnancy, and the possibility of correlating it with the length of the menstrual cycle in any particular case. Jolly¹ has expressed the view that in short cycle cases—for example, twenty-four days—the period of pregnancy extends over eleven cycles, counting from the last menstruation. He terms this the "physiological" period of gestation in the human being, and considers that the reason why pregnancy is terminated as a rule before the lapse of eleven cycles is that the usual case (a twenty-eight-day cycle) is really complicated by other factors, such as the mechanical distension of the uterus.

I should like however, to point out that in my experience the length of the menstrual cycle is not so fixed as many people suppose, we must ask ourselves what is the mechanism of the short cycle case, and whether it is the same as that of the usual twenty-eight-day cycle case. As an example I may record the following case which came under my observation.

A tall healthy girl commenced menstruating at the age of 13½. Her periods at first occurred at intervals of between fourteen and twenty-one days, usually at fourteen-day intervals and lasted for five days. After seven months the type of cycle changed and the periods came on every twenty-eight days and lasted for six to seven days. For about a year after this it happened that occasionally an extra menstrual period occurred in the middle of the month lasting for five days and usually

¹ Jolly, W. A. *Journ. Obstet. and Gyn. Brit. Emp.* vol. 35, 1928.

associated with pain. On two occasions there was no discharge of blood at this extra period, but it consisted of a leucorrhoea lasting for a few days and accompanied by pain. About a year later the menstruation became regular, once every twenty-eight days and lasting for five or six days.

There seems no doubt that if pregnancy were to occur after the establishment of the twenty-eight-day cycle in this case its duration would correspond to the usual, but it is an interesting question as to what duration could be predicted if pregnancy had supervened while the cycle was short. In this connexion the case recorded by Dr S. H. Waddy in the *British Medical Journal* (January 14th, p. 75) may be quoted. The patient underwent curettage and gave birth to a full-term infant 231 days after the operation; she had a short cycle, menstruating regularly every twenty-one days. Dr Waddy took the view that there was here a period of gestation of exactly the duration of ten cycles, that is, 210 days. This is based on the assumption that coitus did not take place for three weeks after the curetting. But if we assume that the curetting took place on a day that would have coincided with menstruation, then the period of pregnancy, reckoning from this menstruation, is exactly eleven cycles, that is, 231 days, which agrees precisely with Jolly's theory. The date of coitus is not known, but if we assume that the fertilization took place at ovulation, which is generally considered to occur about half-way between menstruation, then the actual period of gestation would be ten and a half cycles. On the whole this case may be regarded as lending support to Jolly's theory.

As regards the factors which bring about parturition, there can be little doubt that endocrine influences from the ovary play an important part but we cannot claim to understand the mechanism yet. It has been demonstrated² that the injection of an extract of ovary lowers the blood calcium, and that there is a marked fall in blood calcium preceding parturition.³ Perhaps further investigation of this relationship may lead on to a fuller understanding of the problem, and I hope later to publish results of experiments which I have on hand dealing with this matter—I am, etc.,

PAINLESS LABOURS

SIR,—Several years ago I attended a case similar to those described by Dr Mary DeGaris on October 27th (p. 745). The patient, a primipara, had strong uterine contractions, but no suffering; she remarked that "if these are labour pains, I can't see what people make all the fuss about." Stitching of the perineum, however, caused some pain later.

Referring to uterine contractions, Eden and Holland state that "in animals they are peristaltic, but clinically this is not observable in women." Possibly Dr DeGaris's cases are instances of painless uterine peristalsis. Apparently in cases of primary uterine inertia there is painful uterine peristalsis or uterine colic. Remington Hobbs has pointed out how this uterine colic can occur in the puerperium if there is obstruction at the internal os.

The causes of the ineffectual uterine contractions may be various—a full bladder or rectum, or the patient may be nervous, and worrying about anything from a new nurse to the necessity of finding a new flat (one remembers, of course, that the first recorded case of painful parturition occurred after an eviction!), but the results of the usual treatment with morphine, atropine, and hyoscyne are very good.

A few years ago, when midwives used to send for help very late in the course of a confinement, one used to see, in addition to cases of primary uterine inertia, a number of cases where frequent strong uterine contractions were accompanied by very severe suffering. These were not cases of tonic contraction; there was no obstruction, and with chloroform anaesthesia delivery was comparatively simple.

Recently one has seen fewer of these cases. It is more widely realized that two or more sleepless nights are a

poor preparation for severe muscular effort. The doctor is called in early, a hypnotic secures a night's rest for the patient, the nurse, and the doctor. Uterine contractions, when they begin, are much more effective, and the suffering does not seem to be so acute. Frequently, in fact, the midwife reports later that "the patient had a few food-going pains," and the baby was born, with no need for further medical assistance.

Consideration of this group of cases—whether they are pigeon-holed as spasm of the uterus, lower uterine segment, or cervix, as uterine colic, as altered polarity, or as primary uterine inertia—leads to the inquiry whether it is the hypnotic action of the drugs used or the anti-spasmodic effect that is of more value. Has the result been determined of adding more atropine, belladonna, or hyoscyamine to the usual hypnotics? Has benzoyl benzoate any effect? Does a patient who is delirious while having "twilight sleep" show less spasm than one who is only sleepy?

Perhaps some investigations on these lines will enable us to get back to the "painless labour"—I am, etc.,

London W.10 Oct. 28th.

PESSARIES FOR PROLAPSE

SIR,—The use of pessaries for simple prolapsus uteri raises the all-important question which to employ. Having met with an extraordinary number of septic cases following treatment with the various kinds of ring pessaries, I have every reason to be content with the satisfactory results which have followed the use of the india-rubber cup-and-stem variety.

Only recently I have had under my care a woman with an offensive vaginal discharge, the result of wearing a ring. This had been placed in situ last June, when she was instructed that it would not be necessary to remove it for six months. To give such advice to a patient was, to say the least of it, extremely unfortunate. Even the constant use of a douche by a patient is not sufficient in itself to ensure safety for so long a period, and the results appear to be always the same—that is, a septic discharge with a general lowering of vitality.

As this patient is only one of many who have come to me for treatment, I venture to suggest that the subject is important enough to merit some discussion, as well as suggestions with regard to the use of pessaries in general. Personally I have never found the cup-and-stem pessary fail in this type of case. This result, naturally, is due in the main to the fact that the patient can take it out every night and replace it fresh and clean before rising—I am, etc.,

TUBERCULOSIS BOARDS

SIR,—Now that radical changes are taking place in connexion with the Ministry of Pensions' procedure I should like to call attention to a suggestion I made some years ago.

By way of preface, may I say that I think most tuberculosis specialists who have had much experience on medical boards will agree that a large proportion of the men who are receiving pensions for tuberculosis have not got the disease and probably never had it? I think it was Osler who said that half (or was it 75 per cent.) of the men who were discharged from the army with tuberculosis as their disability never had the disease. Speaking on this point in a paper I read at the Royal Sanitary Institute Congress at Hull in 1923, I said

There has been a gigantic error in diagnosis and there is every reason to believe that the same error is still being made and on very nearly the same scale. The report of the Public Health Committee of the London County Council for 1921 mentions that of 158 men sent to the Brompton Hospital for diagnostic purposes 78.4 per cent were reported as not suffering from tuberculosis.

To give a definite diagnosis of tuberculosis in doubtful cases is a safe and widely adopted policy. It is often right and often wrong. In any case the examiner is on the safe side of the fence whatever happens, but the results in money and man waste are appalling.

From a diagnostic point of view this is the most difficult disease in the whole range of medicine. The history of

² Murvish and Boeman. *Quart. Journ. Exp. Physiol.* 1927 vol. xiii, pp. 11-23, 29-33.
³ McIsaac P. *Brit. Journ. Exp. Biol.* 1928 vol. v No. 3 p. 233.

having had a positive sputum does not help much. We are all familiar with the ease with which a positive sputum could be produced in the army, and with the number of men who 'got their tickets' in this way. We might apply the same remarks to a history of haemoptysis.

Many years ago I suggested to the pensions officials that their methods of dealing with these doubtful cases were all wrong. I suggested with much trepidation and humility that it was not right and just to put on the shoulders of one tuberculosis officer the onus of deciding whether or not certain men had tuberculosis, and that the Ministry should appoint a travelling tuberculosis board, consisting of three specialists in this disease, to examine and decide the fate of these men. I can see little virtue and many faults in the new methods of the Ministry. Special boards are to sit in London, Liverpool, Newcastle, and Glasgow. I venture to say that not a quarter of the men will be able to obey the summons to attend. I submit that if a man really has tuberculosis which originated during his service in the great war he will not now be in a condition to take a railway journey of, say, four or five hours each way.

I have great respect for the permanent officials of the various Ministries, but they often make grave mistakes. This new scheme is one of them. They should bring the special boards to the men, not the men to the boards.

Anent this subject, may I tell a story which has the merit of being true—it can be verified by reference to the man's M.P.A.9. A "permanent official," reporting on a certain case, entered on the man's record card, "This man will require home treatment for the rest of his life and probably institutional treatment later."—I am, etc.,

Hull Oct 24th.

T READMAN

POISONING BY BENZOL VAPOUR

SIR,—In your issue of November 3rd (p. 794) Dr. Gaffrey Carter contributes a note on poisoning by benzol vapour. He begins with the words "These cases are so rare," and continues that in his forensic medicine literature he could only find one recorded case, and that not fatal. In the literature of industrial hygiene such cases are by no means scarce. Benzol poisoning has been very fully surveyed by Greenburg in three issues of the U.S.A. Public Health Reports. Parts I and II are in Vol. 41, No. 27, of July 2nd, 1926 (Part II is 'Acute Benzol Poisoning'). Parts III, IV, and V in the succeeding Nos. 28 and Parts VI, VII, and VIII a fortnight later, in No. 30. Part VIII is a bibliography of 106 references.

If Dr. Carter should wish to read Greenburg's report and has any difficulty in obtaining it, I should be glad to send the three numbers of the U.S.A. Reports. The survey is not confined to benzol poisoning in America. Greenburg's papers, and many others on benzol poisoning, have been noticed in the *Bulletin of Hygiene* published from this Bureau.—I am, etc.,

TRAUMATIC RUPTURE OF SPLEEN

SIR,—I have read with interest Mr. C. J. Cellan-Jones's memorandum on traumatic rupture of the spleen (October 20th, p. 700), as my twenty-five years' surgical experience in Bombay, where, owing to the prevalence of malaria, rupture of the spleen is perhaps the most common intra-abdominal injury, has confirmed me in the belief that delayed haemorrhage and also spontaneous arrest of bleeding are extremely rare. The prognosis, however, is good, provided the surgeon sees the case before too much blood has been lost.

My excuse for writing is that the two cases briefly described here may be of interest to some of your readers, since, though they came under my care at least twenty years ago, I have not subsequently met anything resembling them.

CASE I

A European man aged about 40 was brought to hospital one Saturday about noon. He was very ill and stated that he had been struck with a stick on the left side the previous Saturday night, since when he had had severe pain and several rigors but had continued to work right up to the morning of his admission when he felt he could continue no longer.

The left side of his abdomen was more or less rigid rendering palpation difficult, but an ill-defined mass, in which no splenic notch could be identified, was felt extending from the splenic area down into the pelvis. The left side was dull on percussion but there was no evidence of free fluid in the abdomen. The signs of sudden severe abdominal haemorrhage with the exception of bloodlessness were absent. His condition was such that thorough examination was not possible and successful exploration out of the question. The diagnosis rested between slow haemorrhage from a ruptured spleen caused by a not very severe blow received seven days previously and extreme malarial anaemia combined with splenic enlargement and perisplenitis.

The patient died within two hours of admission. At the necropsy the spleen was found to be considerably enlarged with a tear involving the lower border and extending up the posterior surface, from which a large blood clot resembling a stalactite, extended down to the bottom of the pelvis. There was no free unclotted blood in the abdominal cavity.

This appears to have been a case of slow haemorrhage with a prolonged, though unsuccessful, attempt at spontaneous cure by coagulation, and in all probability haemorrhage was intermittent. Had the patient been kept at rest Nature's efforts might have been crowned with success.

CASE II

An Indian boy, aged 12 or 13 years, was admitted with a tumour extending from under the ribs to the iliac crest on the left side and forwards to near the middle line. The boy was not ill, but complained of discomfort. The history as to origin and when first noticed was vague. On examination the tumour was found to be largely cystic and connected with the spleen.

The left flank was incised and on opening the cyst a large quantity of golden yellow fluid laden with cholesterol crystals escaped. The operation was completed by cutting away as much as possible of the cyst wall and suturing the edges to the wound which healed up by granulation in due course. Microscopic and bacteriological examination threw no further light on the origin.

I think it is possible that this cyst may have originated in an intracapsular haemorrhage caused by some slight forgotten injury.—I am, etc.,

Lieutenant-Colonel I.M.S. (ret.)

Maidenhead Oct. 25th

MEDICAL SICKNESS, ANNUITY AND LIFE ASSURANCE SOCIETY LIMITED

SIR,—In reparting the annual general meeting of this society you did not make clear the position in regard to the election of directors. Believing the general body of members will wish to know the facts, I venture to submit them.

Dr. Martley and I were the two directors retiring by rotation, and we offered ourselves for re-election. Mr. McNeill Love also sought election, thereby creating a contest.

Your readers will, I am sure, concede that in all commercial companies apposition to the re-election of a director and the election of a new man in his place is taken as a vote of censure upon the whole board and the administration of the company's affairs. Since, however, the past year has been the most successful in the history of the company, there can be no excuse for turning out one of the directors in favour of a new man.

As no proxies were issued by the company when sending out the notices convening the annual general meeting, the election was necessarily left to be decided by the votes of those present. Since the membership of the company is nearly 6,000, and such a vote could not, in fairness, be taken as reflecting the feelings of the general body of the members, a poll was demanded. It was ruled by the chairman to take this poll a fortnight later. Proxies were issued with the notice of this poll, and therefore when the members received proxies and a request to vote from the new candidate and Dr. Martley, and no such request from myself, many signed these proxies without realizing that a director would thereby be displaced.

It may be queried why I also did not canvass the electorate. My answer is that I was lulled into a sense of false security by being led to believe up to the last moment, that Mr. Love would withdraw and wait for the next casual vacancy on the board. When, however, one week before the meeting I learned that Mr. Love did not intend to withdraw, it was too late to do anything but write to my personal friends my only chance being to leave the result to the good judgement and good taste of the general body of the members since there was no time to canvass and inform them of my services to the company.

As an indication of these services I may here mention that I was one of the three founders of the present company who brought about its conversion from the old friendly society, on the committee of which I had served gratuitously for several years, that my colleagues on the board had done me the honour of electing me their vice-chairman and chairman of the new Business Subcommittee, and that I have worked hard for extending the company's business in many directions. I may add that I was the youngest member of the board, whose average age is 62.

I retire, therefore, in the belief that if all the members had been aware of the facts they would on principle have voted in my favour. I hope, therefore, that at the next election they will see to it that justice is done and will reinstate me in the office in which I have served them faithfully for so long—I am, etc.,

London W. Nov. 5th

HARRY HILLIARD

CHIMNEY SWEEP'S CANCER

Sir,—May I, through the medium of your columns, make an appeal for some small portions of the chimney-sweep's carcinoma if any surgeon has a case of this description awaiting operation? I am engaged in some investigations, and at the time am particularly anxious to obtain as many specimens as possible of this particular tumour. What I should like is a piece of tumour which includes surrounding skin, if possible also with the small papillomatous nodules, and areas of early involvement. If anyone can, and will, help me in the matter I shall be most grateful if he will communicate with me at the laboratory, St. Giles's Hospital, Brunswick Square, S.W. 5 (telephone Rodnor 4221), when I would arrange to collect the material.—I am, etc.,

London S.E. Oct. 29th.

G. BOUSFIELD, M.B., B.S. Lond.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

The King's Speech

Debate on the Address

PARLIAMENT was opened by the King on November 6th. The Speech from the Throne, after referring to foreign affairs, announced that the Estimates for the coming year were being prepared with strict attention to the need for economy in public expenditure. A bill was proposed to authorize increased borrowing to meet the drain on the unemployment fund resulting from distress in the mining areas. Bills would be presented to reorganize local government in England and Scotland, these would also give effect to the rating reforms and adjust the financial relations between the State and the local authorities. The Speech added that the King's Ministers trusted that the proposed changes in local government and in the relations between the Exchequer and local authorities would enable better provision to be made for the health of the people.

In the House of Commons later on the same day Mr. NEVILLE CHAMBERLAIN gave notice of his intention to introduce at an early date a bill to amend the law relating to local government.

Mr. RAMSAY MACDONALD pointed out that the King's Speech did not mention the *Factories Bill*, though the Government had promised that in previous sessions.

Mr. BALDWIN admitted that an undertaking had been given to introduce the *Factories Bill*. Difficulties of time and the overriding importance of the reforms in rating and local government made that impossible. Mr. Baldwin announced that the Government would ask the House to pass the *Expiring Laws Continuance Bill* and legislation on the traffic services in the Western Highlands and Islands. All private members' time would be taken to Easter, and there would be no ballot for private members' motions.

Dr. FREMANTLE said he hoped that, by the help of all well-wishers of factory and workshop legislation on both sides of the House, they might well be able to find time before the end of the present session to pass the now much needed and frequently promised *Factories and Workshops Bill*. The anticipation in the King's Speech that the proposed changes in local government would enable better provision to be made for the health of the people was not encouraging to those who were keen on thus or that particular measure of social progress.

Still less was the fact that there was no mention of housing at all in the Speech an encouragement. They had had nothing from the Prime Minister in regard to the removal of the subsidy, yet it was vital to the housing movement that they should economize their resources as much as possible. A great deal of the subsidy on houses with a rent of over one guinea a week was being thrown away at the present time. The Prime Minister had referred to the fact that Parliament would have to deal with rent restrictions in the *Expiring Laws Continuance Bill*. The *Restrictions Acts* were at the very bottom of their difficulties in connection with slum property and slum treatment. The development of estates was being delayed because of the exceptional instances of control. Here and there control had held up the erection of houses, and had got in the way of development. It was causing inequalities to owners against profiteering on the part of tenants as opposed to sub-tenants and a great deal of suffering to sub-tenants. There was abundant reason why the subsidy should be further knocked off houses of the highest rental value. By relieving the subsidy on the more expensive houses, which were being adequately provided by private enterprise, so much money would be set free, by which they would be able to subsidize slum clearances. There was no promise in the Speech that the subject of slums was to be dealt with. The Prime Minister said, in December, 1924, when he took office: "We have got to get rid of two things—the shortage in houses and the disgrace of the slums." He (Dr. Fremantle) believed that if they achieved de-control and de-subsidizing they could have improvements in the slums. The report of the Lunacy Commission which came out three or four years ago revealed a system which was insufferably hard on a large number of mental cases. He sincerely hoped that time might be found for legislation on this subject. The country was suffering at the present moment from a vast outbreak of preventable disease—small pox. It had been a mild type of that disease, but the medical profession could give no assurance that it would not become worse. They were sitting on the top of a volcano. He was glad that the great powers had agreed under the aegis of the Health Organization of the League of Nations, to study the question of small pox. A committee had been formed to study it permanently. Of all the civilized countries our own country was one of the most infected with small pox. It was recognized that we were more behindhand in the application of vaccination than any other country, and other countries recognized the necessity for keeping up their quarantine regulations against us. Vaccination had hitherto been left in the hands of the Poor Law guardians, while small pox was in the hands of the sanitary authority. He hoped that in the reorganization of local government it would follow, as a result of the Government's scheme, that the matter of vaccination would be under the control of the larger authorities.

The debate on the Address in reply to the King's Speech continued in the Commons all the week. That in the Lords ended on Tuesday night.

Universities and Colleges

UNIVERSITY OF OXFORD

Theodore Williams Scholarships

On the recommendation of the Waynflete Professor of Physiology the Board of Management has elected Robert A. Beaver New College, to be the Theodore Williams Scholar in Physiology for the year 1928-29.

The Professor of Human Anatomy has reported to the Vice-Chancellor that he recommends that Renatus Kemphorne Queen's College, and Aldwyn B. Stokes B.A. Jesus College, be bracketed equal for the Theodore Williams Scholarship in Anatomy 1928.

On the recommendation of the Professor of Pathology the Board of Management has elected Frank Hawking, University College, to be the Theodore Williams Scholar in Pathology for the year 1928-29.

Radcliffe Scholarship in Pharmacology

The Master and Fellows of University College upon the report of the Professor of Pharmacology have awarded the Radcliffe Scholarship in Pharmacology to Hedley John Barnard Atkins, Trinity College and John Henderson Hunt B.A., Balliol College, equal.

The following are the Degree Days for the present academic year—*Michaelmas Term* 1928: Saturday November 24th, Monday December 17th. *Hilary Term* 1929: Thursday January 24th, Saturday February 16th. *Summer Term* 1929: Saturday March 23rd, Trinity Term, 1929: Thursday May 2nd, Saturday June 8th, Thursday June 27th, Saturday July 20th.

Obituary

SIR HUGH ANDERSON, M A, M D,
F R C P, F R S,

Master of Gonville and Caius College Cambridge

WE have to record with sorrow the death on November 2nd, at the age of 63, after a severe operation, of Sir Hugh Keri Anderson, M D, F R S, Master of Caius College, Cambridge. The outstanding features of his character and of his work are portrayed with intimate knowledge and feeling in the memoir printed below, which has been written at our request by Sir William Hardy, F R S. Sir Hugh Anderson was a true friend to Medicine and to innumerable members of our profession. Although he never practised, his gift of imaginative sympathy enabled him to understand the doctor and the doctor's work. It was characteristic of him that when the British Medical Association met at Cambridge in 1920 he made no public appearances, but welcomed with gracious hospitality the fifty members who lodged in Caius, and dined and talked with them every evening in Hall or Combination Room. He threw himself heart and soul into the arrangements for the Annual Meeting, and showed in many quiet ways, then and at other times, his sympathy with the aims of the Association and his friendship for the Journal.

Anderson's career (Sir William Hardy writes) is something of an enigma. In the first fifteen years of his productive life he proved himself to be possessed of an acute scientific intellect and of an altogether rare quality as a teacher. Why did he not follow the ordinary course, occupy a chair, and become head of a school? Why did he suddenly cease actively to pursue scientific research to be a wise and kind counsellor in affairs, of whom it may be said in literal truth that "there is hardly any great project which has come to fruition in Cambridge for many years but he has been its most inspiring forwarder"? The answer lay in himself. Scientist, man of affairs, artist—he was all of these and the first two found obvious expression. The third, however, cannot be neglected, since it informed and coloured the whole. These three struggled to possess him, and when the conflict was at its fiercest in the early nineties they tore him sorely.

Anderson came to Caius in 1884 as a classical scholar. He held a Saver Scholarship, which was founded by a Canon "for the Promotion of Classical Learning and Taste from Harrow School to be held at Caius College." He at once changed, however, to medicine, and after taking a first class in both parts of the Natural Sciences Tripos, went to St Bartholomew's Hospital to complete his medical course. Somewhere in these years he attended Addenbrooke's Hospital, and cherished memories of the caustic and merciless way in which Sir George Humphrey managed his classes. My recollection of these early years is of musical occasions when Anderson played the 'cello, and of him as an active member of the College Musical Society. After taking his medical degree in 1891 he returned to Cambridge to follow research in the physiological labora-

tory, where he was one of the third generation of Foster's men, the first exemplified by Gaskell and Langley, the second by Sherrington, Adam, Hoad, Rolleston, Shore, the third by Anderson, Rivers, Fletcher, Hopkins, and the fourth by Pavlov, Dale, Elliott.

From 1892 to 1905 there was a steady output of scientific papers, twenty-two in all, bearing Anderson's name. Of their scope and quality I will speak presently. In 1905 the curtain fell, his election to the Royal Society in 1907 being in some sort a posthumous honour so far as his scientific life was concerned. The beginning of the eclipse—for eclipse it was of a brilliant scientific career—is to be found in a simple enough happening, when he first took his turn amongst the Fellows of his College to audit the College accounts. Finance was of the very make up of his being, and from that first auditing followed activities which by 1903 had completely remodelled the College finances and had so increased his influence within the

College that when the headship fell vacant in 1912 the Fellows practically without debate elected him Master. No one was surprised save Anderson himself, and never in the history of any institution was there a more fortunate choice. The date 1905 marks the time when even Anderson's immense industry was unable longer to bear the double burden of College affairs and active research. He did, it is true, and most fortunately for that generation, continue the teaching of science until his election as Master.

In 1909, and again in 1912, when the Hall and Lodge were remodelled, the third side of his nature, his delicate and detailed sense of beauty, enabled him to give peculiar service to his College, which is a vivid memory of those who are able to recollect that time.

The University was not long in discovering the capacity for service which this junior Fellow of Caius possessed. In 1906 he became a member of the University Press Syndicate, in 1908 of the Financial Board, and in 1910 of the Council of the Senate. Thence onward there is a record of ever-

widening public duties, of which the barest enumeration must suffice. He became chairman of the University Press Syndicate, and in that capacity head of a great publishing house. In 1919 Anderson was appointed a member of the Universities Commission, and in 1922 of the University of Cambridge Statutory Commission.

Outside the University he was a director of the London Life Assurance Company, a member of the Commonwealth Fellowship Committee and chairman of the Cambridge Waterworks Company. I reserve to the last an appointment which gave him peculiar pleasure—his election as a governor of Harrow School. Had he acceded to the demands made upon him his activities would have been increased tenfold, but he consciously reserved himself for the service of his College and of his University.

Of the twenty-two scientific papers which bear Anderson's name, nineteen deal with the sympathetic nervous system, and of these fourteen were written in collaboration with Langley. One paper, on the action of the epiglottis, was written with Kanthack, the gifted second professor of pathology in Cambridge whose untimely death took place

THE MASTER OF CAIUS

shortly after 1898, the date of the paper. The collaboration with Langley lasted from 1892 until 1904. It was only in 1902 that Anderson published the first paper of which he was sole author. Looking through these papers after a lapse of years, one is impressed by the immense amount contributed by Anderson to that prolonged analysis of the sympathetic system so steadfastly pursued by Langley, and one can see that Gaskell, Langley, and Anderson started a new movement in physiology. It was a field peculiarly suited to Anderson's extraordinarily high technical skill in dissection, operation, and histology. The series of joint papers begins with the neuromuscular mechanism of the pupil, passes on to the nerves of the large and small intestines, the bladder and generative organs, and ends in the great paper of 1904 on the three classes of nerve fibres—fundamentally distinct in that they are incapable of joining together after section. These classes are the efferent fibres of the spinal cord, the post-ganglionic sympathetic fibres and the afferent fibres. In 1903 Anderson published four important papers, of which he was sole author, on the paralysis of involuntary muscle. The main subject was the so-called paradoxical dilatation of the pupil which follows on injury to the cervical sympathetic. Thus he traced to a state of hyperexcitation of the muscle and not to local action of the ciliary ganglion. In the course of this work he demonstrated reflex dilatation by way of the cervical sympathetic. Two papers alone record work outside the nervous system, and one of these, that on the properties of the peculiarly unstable cosmophilous corpuscles of fish, was of outstanding importance in the controversies of the times.

That is a summary of Anderson's published record, but it by no means exhausts his contributions to science. His reach far exceeded his grasp. Those who worked in Foster's laboratory at any time between 1891 and 1912 will recollect how fertile Anderson was in ideas, how accessible, and how stimulating it was to discuss work with him. No department of physiology seemed to come amiss to him. Contemporaries and pupils alike can bear testimony to the fact that in those years he was a great biologist.

He was, if that were possible, even better as a teacher than as a research worker. While he was lecturer in advanced histology the subject had a character which it has never had since, and everyone who attended his classes, and especially those who came to the small evening classes, will recollect how he never spared himself, and how vividly original in outlook was his mind. It was totally impossible for him to reproduce in class clumsy fragments of textbooks.

Of Anderson's method of work the chief feature was a capacity for taking pains. In the work on the Royal Commission "not a detail escaped him. He toiled day and often night, not only at documents presented to him, but in creating invaluable presentation of statistical and financial information." What a familiar picture those phrases call up to all who knew him intimately! He was apprehensive in this that he felt vividly the possibility and consequences of failure. Sensitive is perhaps the better word, sensitive to those small signs which point to success or failure, especially in dealing with people. Apprehensive and sensitive, yes, but once the course of action was settled in his mind, by the tremendous drill in detail to which he subjected all his ideas, no one could have been bolder.

It is comparatively easy to set out the outstanding features of his career and of his methods, but of the man it is more difficult to speak, and yet for his generation, it was the man that counted. He was so gifted and yet so gentle, so capable of tendering help and so approachable by all who needed help. He was the well-beloved, and on that sure foundation stood his great gifts of service. It is hard to write temperately of him as a personality, hard because any form of words must fall so far short of the truth. "Some of us have lost an old and very dear friend. All of us have lost a wise and kind counsellor." He has great achievements to his credit, but he has also "the number of young people with no claim upon him, in all walks of life, whom he has set upon their road." He might have been a great administrator in wider fields; he might have been a great professor; he was a great Head of his House, and he was a gentleman in the simple significance of the word.

Sir HUGH HENRY ROLLESTON, Bt, Regius Professor of Physics at Cambridge, writes:

The sudden and premature death of the Master of Cambridge is a stunning blow not only to his friends—for they are many, and he was the most lovable of men, ever ready to help others, and entirely oblivious of his own interests—but to the University, and even more so to the Medical School, of Cambridge. The loss of his long-sighted ability and wise judgement leaves a gap which it will be difficult, if not impossible for a long time, to fill, probably few outside its councils know what he meant to the University, and even the numerous committees, syndicates, and boards of which he was a member do not fully represent his influence on its policy and progress. With a wonderful grasp of affairs and long experience he ungrudgingly shouldered heavy burdens of complicated detail, while keeping his activities out of the limelight. His advice was universally sought and carried conviction, but, though clearly expressed, his opinion was given in a most conciliatory manner, for, like the really great, he was essentially modest and sensitive to the feelings of others. He faced illness, of which he had more than his share, with a courage and cheerfulness rarely equalled.

In his younger days a physiologist of great eminence, he maintained a wide knowledge of the natural sciences, and his acquaintance with current work in very different branches and his faculty for anticipating future developments were almost bewildering. Though perhaps on rather different lines, he was, as regards the natural sciences, the real successor of one of the founders of the modern school of medicine at Cambridge, Sir Michael Foster. At the moment of this grievous loss it is difficult to realize, much more so to express, what his death means to his colleagues and friends, for they cannot hope to meet his like again.

Sir WALTER FLETCHER, M.D., F.R.S., Fellow of Trinity College and Secretary of the Medical Research Council, writes:

To Sir William Hardy's most effective sketch of Sir Hugh Anderson's character and work there is little that could be added appropriately here. The medical profession, whether as concerned with its sciences or with its arts, may surely feel proud to number as one of themselves a man who upheld so fully the highest traditions of medicine. He added to knowledge, he greatly served the cause of education, and he abounded in self-sacrificing kindness to others.

It would be out of place to attempt here any detailed notice of the part Sir Hugh Anderson played for a quarter of a century in the development and growth of the Cambridge Medical School. In that, as in other great fields of work, his University owes him an incalculable debt. Here I would only point to a quality which contributed to the value and stability of all he accomplished. Anderson's labours were never in the spirit of partisanship or rivalry. He worked for his College, not as against other Colleges, but because the strength and success of his College served causes he knew to be great. So in his work for the University, he cared deeply for truth for its growth by research, and for the uses to which rightly planned education could bring it. This was the motive force behind all his work, and so in serving his own school of medicine in that spirit he has served the cause of medicine as a whole. Other great and even more direct services he gave as well. For many years he taught and inspired a succession of men who have passed on to work in the various fields of medicine. Very many of these owe to him their first clear ideas of method and sincerity in scientific work, very many owe repeated acts of help and encouragement in their lives. The tale of this kind of service can never be ended or calculated.

In the work of the Royal Commission, and of the Statutory Commission for Cambridge, he took the heavy burden that is now well known, and more recently he has taken the lead in planning the great new developments now foreshadowed for the University Library and some of the biological departments. In these he had a clear view of what medicine has to gain from added strength given to the newer sciences upon which it will have increasingly to draw. He had joined the Medical Research Council a year ago and had looked forward, as the Council had,

to a near future in which relief from his great general burdens might have set him free to enter again more fully into his old delights of helping the growth of biological knowledge

Now there has passed away a great Master of Caius, that College of Harvey and Glisson, whose name must stand proudly among those of any of his predecessors since Dr Caius himself. More happy he was than Caius, in that he never had a personal enemy. Like Caius he was small in physical stature. He died at exactly the same age, and, again like Caius, he was brought home for the last time to his College on the Tuesday after his death in London, passing as he did after a life of Humility and Fortitude out of the Gate of Honour. We can say truly, in thinking of his services to his College and University, what Conrad Gesner wrote of Dr Caius, that he had "consummate judgement, fidelity, and diligence."

Dr H. R. DEAN, Professor of Pathology in the University of Cambridge, writes

It is probable that no single person knew more than a few of the many activities which filled almost every hour of the day for the Master of Caius. The widespread interests of the University, the welfare of his College, the smallest details in the progress of each one of the laboratories of the medical school, the private affairs of his many friends, and even of the almost strangers, who often came to seek his help, were one and all his constant care. While no project for promoting the interests of the University failed to enlist his active support, his enthusiasm found its chief outlet in fostering the advancement of the University departments devoted to the study of the biological sciences. In the department of physiology he maintained a lifelong interest, and he took the keenest pleasure in the growth of the closely related departments of biochemistry and pathology. In the welfare of medical science, in the medical student, and in the difficult problems of the medical curriculum he was always interested, and the Cambridge Medical School owes much alike to the vision which enabled him to forge great schemes for the future of the school and to the meticulous care with which he worked out the smallest details of his plans. His industry was almost fabulous, and when, as often, his interests were deeply engaged, he found it impossible to rest. Elaborate plans, schemes, and proposals were drafted with his own hand with the blue pen and the black Indian ink which he delighted to use. Correction after correction was made, and the whole document was rewritten often three and four times before he was satisfied with the wording and arrangement. He thought little of making several copies of the final draft. During the last few years he did indeed permit a secretary to help him with his work, but he had little liking for typewriting, and his letters to his friends were always written with his own hand.

Busy as he was, he always found the time to help his friends with sympathy, encouragement and well-directed but always kindly criticisms. He was the most accessible of men, and we took our difficulties, great and small, straight to him. We let ourselves into the Lodge at Caius, we never rang a bell. The study door was always open, and from the hall we could see the Master writing at his table. "Come in," he always called. "I want to see you." And up he got from his table with a smile and a look which seemed to expect that your next remark would be something of quite unusual interest. He delighted in helping all who came to him. No problem was too small to arouse his sympathy and interest, and no trouble too great for him to take if he could help a friend. Progressive as he was in thought and policy, there were times when his views and plans met criticisms and opposition. He always considered the opinion of others, and he took great pains to understand the point of view of those who differed from him. He was always unwilling to force his opinions on others, and he thought little of spending hours and days in personal visits and talks with colleagues that he might the better understand their difficulties, and, if possible, construct a solution which all could approve.

His great charm of manner and conversation, his lively interest in everything which mattered to any one of his friends, his wonderful sympathy with the pleasures and

sorrows of his colleagues combined to make him the most delightful of companions. It was his habit to come to one of the laboratories late in the afternoon and to look for one of his friends. It was then, when he had escaped from a long meeting of a board or syndicate, that he liked to go for a short walk. In the summer the walk was generally to the botanical gardens, and the way to the gardens and back to Caius and the route within the gardens was hardly ever varied. In the winter time the walk was in the town, where the shops were just lit up and the windows which displayed old furniture or china or silver were closely scanned and their contents critically discussed, and sometimes a purchase was made. He loved beautiful things and understood them, and he liked to talk about them.

There will be many places in Cambridge where his loss will soon be felt, for he took an active share in so many phases of University life that no one of us will see all the gaps which he has left. In the science laboratories and in the medical school we shall find that we have lost a leader to whom we all have turned for guidance more often perhaps than we have known. All we know now is that we have had a friend who always gave of his best for us and whom we loved very dearly.

The funeral service was held in Caius Chapel on November 6th. Those present included Lady Anderson and other members of the family, the President and other Fellows and former Fellows and many graduate and undergraduate members of the College, together with Sir Ernest Rutherford (President), Sir Charles Sherrington (Past-President), and Sir Richard Glazebrook, representing the Royal Society, Dr W. S. A. Griffith, representing St. Bartholomew's Hospital and College, and the Editor of the *British Medical Journal*, representing the British Medical Association. On the coffin was placed the silver caduceus, the cushion, and the Book of Statutes, presented to his College in 1558 by John Caius, M.D. After the service the procession passed round Caius Court and out of the College through the Gate of Honour. A very largely attended official University memorial service, conducted by the Vice-Chancellor, was held simultaneously in Great St. Mary's Church. The Hebdomadal Council of the University of Oxford, remembering Sir Hugh Anderson's great services to both Universities while serving upon the Royal Commission on Oxford and Cambridge, appointed Sir Charles Sherrington, Waynflete Professor of Physiology, to represent the sister University at the funeral.

LOUIS LAWRENCE CASSIDY, M.B., Ch.B., F.R.C.S.I.,
Gynaecologist, Royal City of Dublin Hospital, Master of
the Coombe Hospital, Dublin.

WE had to announce last week, with great regret, that Dr Louis Cassidy, Master of the Coombe Hospital, Dublin, died on October 27th from injuries received in the hunting field while taking part in the opening meet of the season of the Ward Union Hunt. It appears that he was thrown into a ditch and that his horse fell upon him, when picked up he was unconscious, and he died soon after his arrival at the Mater Misericordiae Hospital.

Louis Lawrence Cassidy was the son of the late Anthony Cassidy, J.P., of the Grann, Enniskillen. He received his early education in his native town, and after he had spent some years at sea and obtained a master mariner's certificate commenced the study of medicine at Edinburgh University, where, in 1908, he graduated M.B., Ch.B. He became a Fellow of the Royal College of Surgeons in Ireland in 1911, and was also a Fellow and a member of the Council of the Royal Academy of Medicine. He was gynaecologist to the Royal City of Dublin Hospital, examiner in midwifery and gynaecology in Dublin University, a former senior demonstrator of anatomy in the Royal College of Surgeons, and gynaecologist to Dr Steevens's Hospital, Dublin. Dr Cassidy was a distinguished lecturer in gynaecology and cancer, and an ardent supporter of the National Cancer Research Campaign, which he helped to organize, and served as its secretary. Years of research into the elusive cause of cancer had fitted him admirably for such a post. At the recent public health congress in Dublin he read a

learned paper on ante-natal care, a subject in which he was greatly interested, and he communicated not a little of his interest to his audience. Not only was Dr Cassidy looked upon in Ireland as one of the foremost specialists in gynaecology, but his profound knowledge of the subject was recognised in Great Britain and on the Continent. He was a member of many medical societies, and his learning brought him into touch with the medical schools of Berlin and Vienna, and with other centres abroad, for a time he was secretary for foreign correspondence of the Royal Academy of Medicine.

Dr Cassidy joined the Royal Army Medical Corps as a captain soon after the outbreak of the war, serving with the forces in Salonika, where he established himself as an authority on malaria. He was a member of the Malaria Commission in the Stuma Valley, and joint author of *Malaria in Macedonia*, a book which threw much light on the campaign against this disease in the Near East. His work in Dublin is widely known. Nearly seven years ago he succeeded Mr McLaverty as Master of the Coombe Hospital, where he distinguished himself by his skill. So great was the success of the National Gynaecological Conference in Dublin on the occasion of the centenary of the Coombe Hospital, about two years ago, that the British Empire Gynaecological Society decided to hold its annual conference in Dublin next March. To Dr Cassidy were due in a large measure the visits of many outstanding men in the medical profession who have lectured in Dublin in recent years.

Of his generosity to the poor perhaps only the poor themselves have a full appreciation, especially those of the Coombe area. He was always willing to give financial help to deserving objects, and to any scheme for the advancement of his profession. He was a member of many organizations in the city, including the All-Ireland Polo Club. Dr Cassidy was respected by his colleagues in the medical profession, esteemed by the public at large, and loved by those in need. In his brilliant attainments, scrupulous sense of honour, and courtly manners, he was an Irish gentleman and scholar of the best type. He was only 51 years of age, and leaves a widow, a son, and a daughter, with whom deep sympathy is felt in their bereavement.

JOHN BLACKBURN SMITH, C B,

Major General I M S President of the Medical Board of the India Office

We have to announce, with great regret, that Major-General John Blackburn Smith, C B, Bombay Medical Service (retired), the president of the Medical Board of the India Office, died suddenly at Cork, where he had gone on short leave, on November 2nd at the age of 63. He was born on January 25th, 1865, the son of the late Rev John Anderson Smith of Lurgan, Armagh, and educated at Queen's College, Cork, graduating as B A in 1887, M B, B Ch, and B A O in 1888, and M Ch in 1889, in the Royal University of Ireland. Subsequently, in 1907, he took the diplomas in tropical medicine and public health at Cambridge. He entered the I M S as surgeon on September 30th, 1889, attained the rank of colonel on September 3rd, 1918, and was promoted to major-general on June 26th, 1920. He retired on January 22nd, 1923, and in August of that year was chosen to succeed Sir Havelock Charles, G C V O, as president of the Medical Board of the India Office, holding that post at the time of his death. During the war he served in Egypt from January, 1915, to April, 1916, and on the North-West Frontier of India, in the Mahsud operations, from May to August, 1919. He was mentioned in dispatches in the *London Gazette* of June 22nd, 1916, and May 18th, 1918, and was decorated with the C B on June 4th, 1918. He was appointed Honorary Physician to H M the King on January 25th, 1919, and received the C I E on January 1st, 1922.

General Smith had much experience of both military and civil employment in India. For many years he served as civil surgeon of Poona, the most important station in the Bombay Presidency, and after the war was appointed Deputy Director of Medical Services in the Eastern Command. For the last five years in the India Office, as

president of the Medical Board, he had rather a difficult job in the present state of transition of all things Indian. One of his most important duties was, as a member of the Selection Board, to choose men for appointment by nomination to the Indian Medical Service, a task for which he was specially fitted by his long experience and mature judgement. He was very popular both with his contemporaries and with junior officers. *Multis ille bonis flebilis occidit.*

In 1896 General Smith married Letty Mayne, daughter of the late W R Nelson of Belfast, who survives him. He leaves also three sons and one daughter.

One of General Smith's most intimate friends contributes the following note:

In the summer of 1923 General Smith was selected from a number of senior officers for the very responsible post of medical adviser and president of the Medical Board at the India Office, in succession to Sir Havelock Charles, Bt. Here once more his quiet conscientious work proved of inestimable value to his service at a most critical time, when the interests of the Indian Medical Service are being steadily sacrificed to political clamour in India. He never wavered in his loyal support of what he considered to be right in face of the insurmountable obstacles he had to face, and it was certainly not for any want of his persistent advocacy at the India Office that the Indian Medical Service, which has long been regarded as the greatest the world has ever seen, has not been able to recover from the repeated blows inflicted on it ever since the so-called reform scheme came into operation. In this uphill struggle his courtesy, modesty, great powers of application, and unswerving loyalty endeared him to all who had the privilege of working with him, and there is no doubt that his unceasing labours at the India Office caused him to age rapidly during the last few years and hastened his untimely end, a year before he would have retired to a well-earned rest, and before he had received any recognition of his labours at the India Office, which might fittingly have been bestowed when he first succeeded to his responsible duties there. The Indian Medical Service has lost in General J B Smith a greatly respected and loved officer of sterling character, who has well earned the highest praise, "Well done, good and faithful servant."

SIR G STEWART ABRAM, M B, B Ch,

Senior Physician Royal Berks Hospital

By the death of Sir Stewart Abram the town of Reading has lost one of its leading citizens, and the local medical profession one of its distinguished members, who leaves the memory of a well spent life devoted to the service of his fellow men.

George Stewart Abram received his early education at Merchant Taylors' School, and entered Caius College, Cambridge, where he gained honours in the natural sciences tripos. From the University he proceeded to University College Hospital, London, and in 1891 graduated M B, B Ch Camb, and obtained the diplomas M R C S, L R C P. In 1893 he settled in Reading and built up an extensive practice. In 1904 he was elected to the staff of the Royal Berks Hospital, of which later he became the senior physician. In due course he filled the office of president of the Reading Pathological Society, to which, on retiring from office, he presented a striking badge of "Imhotep," the Egyptian deity of medicine, as a souvenir of his presidency.

During the war he held the rank of major in the R A M C (T A), and took charge of the Wilson War Hospital at Reading, where some 10,000 patients passed through his hands. To the British Medical Association he ever rendered loyal service, being a member of the Reading and District Branch Council from 1900 to 1902, and of the Oxford and Reading Branch Council on and off between 1903 and 1920. He was elected vice-chairman of the Reading Division in 1913, and chairman in the following year.

A keen politician, Abram was a hearty supporter of the Conservative party, and for a time served as president of the Reading Conservative Association. To the civic life of Reading he rendered invaluable service, being for over

thirty one years first a town councillor and afterwards an alderman of the borough. He was chairman of the health committee of the Reading Education Committee. He filled the office of mayor in 1919-20, and in January, 1922, much to the gratification of his fellow townsmen, received the honour of knighthood. It may be said in brief that *omne quod tigit ornavit*. Amid his many professional, political, and civic activities he found time for sport, and participated in many tennis tournaments. In later years he became attracted to the drama, and took an important part in the Reading pageant, which was organized during his mayoralty and largely through his inspiration.

Some years ago he was attacked by a grievous malady, which he bore with characteristic fortitude, carrying on his exacting duties with admirable self-forgetfulness. A few weeks ago his malady reached a critical stage and the end was obviously approaching. On the night before his death a special meeting of the Reading Town Council was summoned for the single purpose of conferring upon him the highest honour that could be paid to a citizen—namely the honorary freedom of the borough. At this meeting eloquent tributes were paid to the character and services of the new freeman. At the close of the meeting the mayor hastened to Sir Stewart's bedside and presented to the dying alderman the parchment recording his admission to the honorary freedom of the borough. Five hours after signing the roll the new freeman breathed his last.

Sir Stewart Abram married, in 1883, Ethel May, daughter of Mr. T. F. Rider, M.V.O., to whom, with his son and two daughters, deep sympathy is extended.

J. B. H.

We are indebted to another colleague ("W. B. S.") for the following appreciation. Possessed of great personality and absolutely indefatigable energy, Abram did not confine his talents, which were many, purely to professional work. Shortly after he came to Reading he was elected to the town council, on which he served for very many years, taking the keenest interest in all its activities. He was also a governor of Reading School, a member of the court of the university, an ex-president of the Reading Pathological Society, and a member of very many charitable, welfare, and athletic association committees. He led a very active political life, and took a leading part in the organization of the Conservative party in the town, for many years he was chairman, and afterwards president, of the local Conservative and Unionist Association. A fluent and graceful speaker, he was always in great request at both political and non-political gatherings. In spite of severe disabilities due to progressive disease he carried on his ordinary work actively, cheerfully, and courageously until a week before his death. Abram loved his work and he loved his town. It can truly be said that few men have laboured so unceasingly for the good of his fellows. His untiring energy was amazing and his life's work has indeed been well done.

FRANK JOSEPH WETHERED, M.D., F.R.C.P.,

Consulting Physician to the Hospital for Consumption and Diseases of the Chest, Brompton, late Physician to the Middlesex Hospital.

We regret to announce the death, on October 28th, of Dr. F. J. Wethered at the age of 68.

Frank Joseph Wethered, who was the son of Joseph Wethered of Clifton, Bristol, was educated at Clifton College and the London Hospital. In 1885 he obtained the diplomas M.R.C.S. (Eng.) and I.S.A., and graduated M.B. (Lond.), in the following year he became M.R.C.P., and proceeded M.D. in 1888. He obtained the degree of M.D. (Bristol) in 1913. He devoted some time also to study abroad, principally in Berlin and Vienna, and was appointed medical registrar and demonstrator of practical medicine at the Middlesex Hospital in 1892. He was elected assistant physician to this hospital in 1899, and physician in 1913. He was also a member of the staffs at the Brompton Hospital for Consumption and St. Saviour's Hospital. Wethered was always interested in medical jurisprudence, and often visited the Law Courts and the Old Bailey, he became lecturer on the subject in the Middlesex Hospital

Medical School in 1896. He was also attracted by insurance work, and was for some time physician to the Equity and Law Life Assurance Society. He was elected a Fellow of the Royal College of Physicians in 1895, and served as member of the Council and examiner in medicine. He was very keenly interested in medical literature, acting for some years as medical referee to the *Lancet*, and he himself wrote in a clear, interesting manner. He gained the second prize in the King's competition with an essay on "A sanatorium for consumption."

Wethered was a man of very kindly disposition, most popular with his friends, and a conscientious worker. He had a moderate practice, but, possessing private means, he did not exert himself to make it very extensive. He enjoyed all the work he did, preserving always a very open mind, but his temperament was not altogether suited to the uncertainties of the medical life. During the war he took very seriously his position at the Third London General Hospital, where he served as captain in the R.A.M.C. (T.F.). He married in 1889 the daughter of Edward Howan, fond of entertaining, he exhibited a charming side of his personality in his home life.

He had one daughter, to whom he was devoted, and her sudden and tragic death in 1918 was a shock from which he never really recovered. He resigned all his appointments in London, and retired to Falmouth, where he undertook a small amount of local consultant work, and was consulting physician to the Royal Cornwall Infirmary, Truro. He was fond of outdoor occupations, and after his retirement to Cornwall he was able to devote time to his favourite recreation of sea-fishing. During the last ten years of his life he practically never visited London, and most of his old friends never saw him again, but he will be remembered by a wide circle as a very kindly soul of charming personality.

Dr. HENRY EDWARD DAVISON, who died at his residence, The Brow, Wylam-on-Tyne, on October 15th, after a short illness, had been a well-known figure in the Newcastle district throughout the greater part of his life. He received his medical education at Newcastle-on-Tyne College of Medicine, obtaining the diplomas M.R.C.S., L.R.C.P., and graduating M.B., B.S. (Durham), with honours, in 1899. A year later he became B.H., and in 1901 proceeded M.D. and obtained the D.P.H. For a period he held a resident post at the Royal Victoria Infirmary, Newcastle, and was afterwards for two years resident medical officer at the Newcastle Dispensary. Subsequently he started practice locally, but relinquished his extensive practice during the war to undertake neurological work in London, ultimately assuming charge of the Ministry of Pensions Neurological Clinic and being appointed president of the Special Neurological Board of the Ministry. While in London he took a leading part in the affairs of the Psycho-Neurological Society. He subsequently returned to private practice and settled at Wylam, where he won wide popularity. He was a member of the British Medical Association. Dr. Davison married the second daughter of the late Dr. Armstrong, who was for forty years medical officer of health for Newcastle and was one of the founders of the medical college in that city. He is survived by two sons and a daughter.

Dr. SAMUEL IAN HAMILTON REID, who died at the age of 27, on October 16th, at Queen Mary's Hospital for the East End, Stratford, E., after an operation, had been resident medical officer there for about ten months. He received his medical education at the Queen's University, Belfast, graduating M.B., B.Ch., B.A.O. in 1923, and was admitted F.R.C.S. (Ed.) last year. He had held a succession of resident hospital appointments in Belfast, at the Salford Royal Hospital, at the South Devon and East Cornwall Hospital, Plymouth, at the West London Hospital, and at St. Peter's Hospital, Covent Garden. His death has caused deep regret among his colleagues and others associated with him, he was held in high esteem as a surgeon of considerable promise, and had won the warm affection of many friends. His brother is in practice at Plymouth.

Dr. **IRVING JAMES MILNE**, who died suddenly from heart failure on November 2nd, at the age of 63, had been in practice at Mirfield, in the Dewsbury district of Yorkshire, for over thirty years, and had been medical officer of health for Mirfield since 1906. A native of Aberdeen, he received his medical education at the University there, graduating M.B., C.M. in 1890, and proceeding M.D. in 1897. The greater part of his professional life was spent at Mirfield, where he built up an extensive connexion, yet found time for a variety of other activities. His work as medical officer of health was recently the subject of a complimentary message from the district council. Dr. Milne was also honorary surgeon to the Mirfield Memorial Hospital, and medical officer to the Liversedge and Mirfield Joint Infectious Hospital, the Community and College of the Resurrection, and the post office. He was keenly interested in child welfare work, and devoted as much time as possible to the Mirfield centre. During the war he was attached to a base hospital at Dewsbury as medical officer. In the affairs of his profession he played an active part, and as a member of the British Medical Association had served upon the executive committee of the Leeds Division, while in the Society of Medical Officers of Health, of which he was a Fellow, he had held the office of president. He was a popular figure in the Mirfield district, both among his colleagues and with the general public, and his death has caused deep regret. Dr. Milne was unmarried, his brother, Dr. J. Adam Milne, is in practice in Nottingham.

Dr. **RODERICK MACLEOD**, who died from pneumonia at Middleton St. George in the county of Durham on October 26th, at the early age of 30, was a native of Stornoway, Isle of Lewis, and received his medical education at Aberdeen University. During the war he enlisted in the Royal Engineers, and was twice wounded and gassed in France, being ultimately discharged as medically unfit. He completed his studies in 1921, and graduated M.B., Ch.B., settling in the Darlington district in practice at Middleton St. George about three years ago, being also honorary medical officer to the Roper Convalescent Home. Dr. Macleod was an active member of the Darlington Division of the British Medical Association, and was a popular figure among his colleagues, one of whom writes: "He was an undoubted success in general practice—kindly, approachable, and efficient—and was beloved of his patients and friends. His illness was a sudden tragedy, striking him down while in good health, he failed to rally from this, his second attack of pneumonia and it seemed that the effects of gas in the war had undermined his resistance. His funeral was an impressive tribute to the respect in which he was held among colleagues, patients, and friends, and he will be sorely missed in the neighbourhood. Much sympathy is felt for his widow and for his aged parents, who are thus bereaved of their only son."

The following well-known foreign medical men have recently died: Professor **LUIGI MINGHIOALI** of Milan, aged 78, Senator of Italy, Counsellor of State, and formerly professor of obstetrics and gynaecology at Sassari, Catania, Pavia, and Milan, where he founded a cancer institute; Professor **LUIGI SABBATINI**, director of the Institute of Pharmacology at Padua, aged 65; Professor **GIUSEPPE SILVIO TONINI**, who recently resigned the chair of neuro-psychiatry at Bologna, aged 70; Dr. **GUSTAV V. SCHLEICH**, professor of ophthalmology and rector of the University at Tübingen, aged 71; Dr. **WILHELM FLEISS**, author of works on the periodicity of life and the reflex relations between the nasal mucous membrane and other organs, especially the female genitals, aged 69; Dr. **FLORENT JANSSENS**, doyen of the medical faculty of Louvain; Dr. **CHARLES LEE SUMMERS**, professor of pediatrics in the Maryland school of medicine; Dr. **OMÉLIAVSKY**, an eminent Russian bacteriologist; Dr. **WILLIAM SHEPPEGRELL** of New Orleans, author of a work on hay fever and asthma and of numerous articles on diseases of the ear, nose, and throat, aged 68; Professor **D. S. FAUST**, a pharmacologist of Basle, aged 58; Dr. **HOFFMANN**, a medical jurist of Berlin, and Professor **WALTERHOFER**, a haematologist of Berlin, aged 47.

Medical News.

THE annual dinner of the Society of Medical Officers of Health will be held at the Piccadilly Hotel on Thursday, November 15th, at 7.30 p.m. Ladies are invited. Members and candidates nominated for election intending to be present are asked to give early notice to the Executive Secretary, 1, Upper Montague Street, W.C.1. Applications should be accompanied by a payment of 12s. 6d. for each ticket. It must be before Monday, November 12th, after this date the cost will be 15s. for each ticket.

THE Aberdeen University Club, London, will hold its eightieth half-yearly dinner at the Frocadero Restaurant on Thursday, November 22nd, with Lord Moston, Chancellor of the University, in the chair, and with the Earl of Birkenhead, Rector of the University, as principal guest. The secretary's address is 9, Addison Gardens, Kensington, W.14.

At the adjourned annual general meeting of the Medical Students' Annuity and Life Assurance Society, Ltd., held on October 22nd, Mr. R. J. McNeill Love and Dr. F. C. Martley were declared duly elected as the result of the poll for two directors.

At the meeting of the Medico-Legal Society to be held at 11, Chandos Street, W.1, on Thursday, November 22nd, at 8.30 p.m., Dr. L. A. Weatherly will read a paper on juvenile psychologic delinquencies—their origin and treatment, which will be followed by a discussion.

THE Central Midwives Board for England and Wales, at a meeting on November 1st, with Sir Francis Champneys in the chair, granted permission to the guardians of the West Dorset Union for the training of ten pupils at a time at the Mill Road Infirmary, Liverpool. Approval as lecturers was granted to Drs. C. B. Robson, A. K. H. Kounoth, and J. K. Timothy. The Board decided that all candidates submitting certificates of birth, baptism, or marriage, which had been tampered with in any way, be debarred from sitting for examination for at least three months after the presentation to the Board of such certificate or certificates. The report on the work of the Board for the year ended March 31st, 1928, was approved, and signed by the chairman and secretary for forwarding to the Ministry of Health.

THE first Argentine Congress of Surgery will be held next week at Buenos Aires under the presidency of Dr. Armando Marotta, professor of clinical surgery in that city.

THE next award of the Swiney Prize—a silver cup of the value of £100 and money to the same amount—to the author of the best published work on medical jurisprudence will be made in January, 1929, on the eighty-fifth anniversary of the testator's death. The award is made jointly by the Royal Society of Arts and the Royal College of Physicians, and any person desiring to submit a work, or to recommend any work for the consideration of the judges, should do so by letter addressed to the Secretary of the Royal Society of Arts, John Street, Adelphi, London, W.C.2, not later than November 30th, 1928. The silver cup to be presented on this occasion was designed by Mr. Edward N. H. Spencer, whose design was awarded first prize at the society's 1928 competition of industrial designs. The finished cup has been included with the works of living craftsmen as part of the Loan Exhibition of Oxford College Plate which is on view at the Ashmolean Museum, Oxford, from November 7th to 23th.

THE Fellowship of Medicine and Post-Graduate Medical Association announces that on Monday, November 12th, Dr. H. C. Semon will lecture for the Fellowship on "Some basic remedies in diseases of the skin" at the Medical Society of London, 11, Chandos Street, Cavendish Square, at 5 p.m., and that on the same date, at 4.30 p.m., a clinical demonstration will be given by Mr. Williamson Noble at the Central London Ophthalmic Hospital. On the following Wednesday, at the Wellcome Museum of Medical Science, 33, Gordon Street, W.C., Colonel L. W. Harrison will give a demonstration on syphilis now and twenty years ago. The above lectures and demonstrations are free to members of the medical profession. Miss Davies Colley and her colleagues will give a clinical demonstration, free to women graduates only, at the South West London Hospital for Women, 103 South Side, Chapham Common, on Friday, November 16th, at 2 p.m. A three-weeks course in medicine, surgery, and gynaecology given by the staff at the Royal Waterloo Hospital for Women and Children, begins on November 12th, and on the same day will open a special short course in pathology at St. Mark's Hospital. There will be a course in ophthalmology at the Royal Westminster Ophthalmic Hospital from November 12th to December 1st, and a course in urology at St. Peter's Hospital from November 19th to December 1st. For these hospitals from the late afternoon there will be a course in neurology at the West End Hospital for Nervous Diseases, daily from

5 p.m., from November 19th to December 15th. Throughout the month there will be a course at the London Lock Hospital in venereal diseases. Syllabuses and particulars of the general course of work under the Fellowship scheme are obtainable from the Secretary, 1, Whitpole Street, W 1.

THE first evening meeting of the new session of the British Institute of Philosophical Studies will be held at the Royal Society of Arts, 13, John Street, Adelphi, W.C.2, on Tuesday, November 13th. Dr C. S. Myers, F.R.S., will take the chair at 8.15 p.m. Mr Morris Glusberg, D.Litt., will lecture on race and civilization. A limited number of seats are reserved for members of the public for which application should be made to the Director of Studies, British Institute of Philosophical Studies, 88, Kingsway, London, W.C.2.

THE Ministry of Health has issued a booklet, obtainable from H.V. Stationery Office (price 4d net), on regional water committees, explaining briefly the reasons for the constitution of such bodies and the work they should undertake. It is pointed out that the more readily accessible sources of water supply have, generally speaking, been appropriated while consumption is growing, so that if the remaining sources are to be made available cheaply and without dissension, systematic foresight is desired. There is no occasion for general alarm, but in some areas the question of future sources demands serious consideration. The most practical way of meeting the demand for a national allocation of water resources, it is suggested, is by the formation of regional water committees, which will ascertain the needs of each district in a region and formulate a policy for meeting requirements. Such regional findings can then form the basis of a national policy. A region should comprise the districts of 'water undertakers'—local authorities or companies—who are, or are likely to be, concerned in the same general sources of supply or whose interests are otherwise closely connected, a regional committee, being purely advisory and having no executive power, need not be composed of representatives in strict numerical proportion to the importance of the undertakings they represent. The most important element is that it should contain persons capable of dealing with the problems before it. It is contended that considerable savings could be effected by such bodies. A regional committee should prepare a programme providing for measures in detail for twenty years ahead, and in broad outline for about fifty years ahead; it should be kept in being for the periodical revision of its programme in the light of the latest developments. The pamphlet gives an outline of the manner in which the work of a committee should proceed.

THE *Medical Art Calendar* for 1929 is, like its predecessors, an attractive, clearly printed, and well got-up volume. The plates, of which there are twenty-seven, are photographic reproductions of famous paintings, engravings, and etchings dealing, directly or indirectly, with medical subjects. They are intelligently chosen, clearly reproduced, and in most cases beautiful. They can be readily detached and framed separately, and nearly all of them are well worth it. The *Calendar* can be obtained from Mr Kruseman, 8 Gravenhage, Noordeinde 91, Holland, price 6s post free.

A LIST of British and American doctors practising in various towns in Continental Europe and Northern Africa is published by the Continental Anglo-American Medical Society, and free copies may be obtained from the honorary secretary, Dr B. Sherwood Dunn, 54, Boulevard Victor Hugo, Nice, France. This society was founded in 1885, and for nearly forty years has published periodically lists of medical practitioners in Europe and North Africa who speak English.

THE returns of the six European countries—namely, England and Wales, Sweden, Finland, Denmark, Switzerland, and Italy—for which fairly reliable data of the incidence of epidemic encephalitis since 1920 are available, yield the following figures: 7,697 cases in 1920, 4,649 in 1921, 1,273 in 1922, 2,205 in 1923, 6,196 in 1924, 3,766 in 1925, 2,991 in 1926, and 2,168 in 1927. The same countries had 1,050 cases during the first half of 1928.

TYPHUS fever was less prevalent in Europe during the first half of 1928 than during the corresponding period of any other year since the war. The decrease was most marked in Rumania, and there was a considerable decrease also in Poland. On the other hand, there was an increased incidence in Lithuania and Latvia. In the Union of Socialist Soviet Republics the decrease was most marked in Central Russia and in the Ukraine. In Western Russia the incidence was about the same as last year. In Korea typhus was more prevalent in the early part of 1928 than in previous years.

THE death rate in the Federated Malay States has risen from 29.22 per thousand in 1926 to 32.11 in 1927. Dr R. Dowden, principal medical officer of the Federated Malay States, in his annual report for last year, attributes this increase to the influx of very large numbers of immigrants and their dependants who were not acclimatized and who

were frequently of poor physique. Among contributory causes were outbreaks of cholera, plague, small pox, and beriberi. In the State of Pahang, where the increase in the death rate was most marked, the vitality of the population was impaired by floods which occurred at the beginning of the year, the destruction of crops and vegetable gardens caused an outbreak of beriberi, and many deaths from malarial fever followed. Every effort was made to meet the situation by the health services, and the Medical Research Institute issued large quantities of rice polishings extract, but it was impossible to control these diseases over large tracts of undeveloped country with the communications broken down. Dr Dowden suggests that the outbreak of beriberi shows how very narrow is the margin between health and disease among Asiatics, and also how they react immediately to any interference with the vitamin content of their food supplies. He adds that, in spite of all that can be done, the population, of all races, are increasingly using polished rice.

THE KING has granted his licence and authority to Major Basil H. C. Lea Wilson, R.A.M.C., P.M.O., Egyptian Army, to wear the insignia of the third class of the Order of the Nile conferred upon him by the King of Egypt in recognition of valuable services rendered. Permission has also been granted to Dr Andrew Copland to wear the insignia of the third class of the Order of the Brilliant Star of Zanzibar conferred upon him by the Sultan of Zanzibar for valuable services rendered.

DR THOMAS G. NASMYTH of Edinburgh has been appointed Deputy Lieutenant for the city and county of Edinburgh.

PROFESSOR P. G. UNNA has been elected an honorary member of the American Medical Association and Dr Ernest Fuchs, professor of ophthalmology, and Dr Wilhelm Iatzko, professor of gynaecology at Vienna have been nominated honorary members of the Academy of Medicine of Buenos Aires.

DR NETTER has been made a grand officer and Dr Darier a commander of the Legion of Honour.

Letters, Notes, and Answers.

All communications in regard to editorial business should be addressed to **THE EDITOR, British Medical Journal, British Medical Association House, Tavistock Square, W.C.1**.

ORIGINAL ARTICLES and LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* alone unless the contrary be stated. Correspondents who wish notice to be taken of their communications should authenticate them with their names, not necessarily for publication.

Authors desiring REPRINTS of their articles published in the *British Medical Journal* must communicate with the Financial Secretary and Business Manager, British Medical Association House, Tavistock Square, W.C.1, on receipt of proofs.

All communications with reference to ADVERTISEMENTS, as well as orders for copies of the *Journal* should be addressed to the Financial Secretary and Business Manager.

THE TELEPHONE NUMBERS of the British Medical Association and the *British Medical Journal* are *MUSEUM* 9363 9362 9363, and 2363 (internal exchange, four lines).

THE TELEGRAPHIC ADDRESSES are: EDITOR of the *British Medical Journal* *Atiology Westcent London*.

FINANCIAL SECRETARY AND BUSINESS MANAGER (Advertisements, etc.) *Articulate Westcent London*. MEDICAL SECRETARY *Meducera Westcent London*.

The address of the Irish Office of the British Medical Association is 16 South Frederick Street, Dublin (telegrams *Bacillus Dublin* telephone 62550 Dublin) and of the Scottish Office 7 Drumsheugh Gardens, Edinburgh (telegrams *Associate Edinburgh* telephone 24361 Edinburgh).

QUERIES AND ANSWERS

SEBORRHOEA OF THE SCALP

DR HENRY WALDO (Clifton Bristol) in response to Dr I. B. McCallum's request for suggestions in the treatment of seborrhoea of the scalp (November 3rd p. 828) writes: As greasy applications are disliked sulphurous acid B.P. if rubbed into the scalp daily, will benefit it and soon cure it. The scalp should be washed in soap and water once a week always.

DR L. IVAN M. CASTLEDEN (London N.W.1) writes: I have found the best basis for such an ointment to be a combination of soft paraffin and coconut oil as suggested by Whitfield and A. M. H. Gray. A useful formula is: A.o. anlicyl gr xv, anlipn sublim gr xv, ol. lavand mly paraffin moll 3ij, ol. cecoli uncerif ad 3j. It is not so messy as paraffinum melle alone and is easily washed out the only disadvantage being that it gets rather soft in warm weather, so should be dispensed in screw top pots. As an alternative formula the following has proved useful. Resorcinu

et ac salioz iū 3as, ap vial rect 3ij, solve Adde Lij carb
deleg 5j paraff liq alb 3ij This lotion replaces brilliantine
for male patients, the oil and spirit mixing easily when shaken
before a bottle with spritlike cork. Less oil can be used if
desatrol as in the case of female patients. Research, although
excellent cannot be used by those with very fair hair, as it tends
to stain.

CHRONIC URTICARIA

"W T P" in reply to "Inquirer a" request for suggestions for
the treatment of chronic urticaria (October 20th, p 732), reports
consistent success from the use of oilatum sodum lactate
tablets. He prescribes at least four tablets daily, as follows:
one on rising, one an hour before the midday meal, one an hour
before the evening meal, and one on going to bed.

LBN AT BIRTH

Dr W L HUNNARD (St Leonards-on-Sea) writes: While taking
charge of the practice of a friend a baby was born and lived at
least one week weighing only 1 lb. During that time it had
gained in weight, cried more strongly and began to suck the
mother's breast. I do not know whether it still survives. It was
born at the beginning of the seventh month of pregnancy.
I should like to know if this is an unusual weight for a child
living at least seven days.

DELAYED MENSTRUATION

Dr ROSE CRESAY (London, W 1) in reply to "A T's" inquiry
(November 3rd, p 828) as to treatment of an obstinate case of
delayed menstruation in a stout girl aged 25 writes: I would
advise "A T" to try static electricity applied by means of a
vaginal or rectal electrode. The treatment is painless. In a very
similar case this treatment proved successful in my hands. The
static machine must be a really powerful one.

EGG PRESERVATIVES

"R B G" asks if any harm to the consumer can result from
eating eggs preserved in waterglass which contains silica. The
custom of such preservation is widespread, and presumably,
if the process is harmful, some evidence to this effect exists.
There is bound to be a certain amount of absorption of the silica,
and this may, or may not, have some action on the egg or upon
the gastric juice.

INCOME TAX

Obsolescence of Car

"J C" bought an 119 h p V car in 1920 for £400 and sold it in
1925 for £18 when he purchased a second hand 121 h p D car for
£200. On that transaction he was allowed a deduction for
income tax purposes of £200-£18=£182. In 1927 he sold that
car for £55 and bought a 10 h p R car for £250. Depreciation
has been allowed in recent years.

* * The statutory provision is Ru's 7, Cases I and II,
Schedule D, which allows as a deduction so much of any
amount expended in replacing a car which has become obsolete
as is equivalent to the cost of the car replaced after deducting
the total amount of the depreciation allowances and the sum
realized by the sale of the car. The difficulty is whether the net
expenditure of £250-£55=£195 was not partly laid out in
improving, and not merely in replacing the car equipment.
On that point we think that "J C" can properly disregard the
temporary lowering of his car standard and refer back to the
original V car and its cost as showing, that, on the whole, there
has been no capital expenditure involved in the two car transac-
tions combined. Equity is undoubtedly on his side, and he
might well press the matter to an appeal if necessary.

New Partnership—Cash Basis

"T H G" refers to a reply in our issue of June 30th last and
explains that the Inspector of taxes now proposes "as a com-
promise," to include in the accounts of the partnership for
the first year only the cash received in that year for the fees
earned before the beginning of the new firm. Is he right in
refusing the compromise?

* * We can see no logical justification for the basis proposed
and are clear that the new firm is not chargeable to tax on those
fees. Perhaps the Inspector would agree to confine the cash
basis without qualification. On that basis the amount of the
fees in question would be brought into the computation but the
unpaid fees outstanding would be omitted. The basis of division
of the net earnings of the practice as so calculated would, of
course, be that laid down in the partnership agreement.

Assessment of Interest

"H J D" writes: I have had a holding of War Stock for some
years and in August 1927, bought a further holding of the same
stock. The Inspector of taxes has made the assessment for the
year 1928-29 on the amount received on the original holding in
1927-28 plus the amount receivable on the additional holding in
the year 1928-29. Is this correct?

* * Section 30 (1) of the Finance Act 1926 provides that
where a person acquires an addition to any source of such
profits or income, income tax to respect of the income from
the addition to that source shall be computed separately.
The result is that while income from the original holding is

computed on the previous year's basis the interest on the
additional holding is computed on the basis of the actual year.
It is, of course, also provided that the converse takes effect on
sale of part of a holding.

Employee Spending Part Time on Private Work

"R P M" explains that, being unable to replace a boy formerly
employed entirely for professional purposes, he and his partner
have engaged a married man who will spend part of his time
cleaning cars and doing odd jobs and part on housework and
gardening. Seeing that his employment is necessitated by the
professional work—(1) Is a licence duty payable in respect of his
employment? and (2) Can the whole of the cost be charged for
income tax purposes?

* * (1) Yes. (2) No, only the amount arrived at by taking
a proportion according to the ratio of professional to private
employment.

LETTERS NOTES ETC

MEDICAL GOIF

The first week-end meeting of the London Irish Medical Golfing
Society was held on October 27th and 28th, when there were
about fifty members present. Mr Canny Rival presided at the
annual dinner in the Granville Hotel Ramsgate, on October
27th, when Dr Roll Cressy who was the guest of the evening
was elected an honorary member. A successful auction sweep
was held. Dr George Campbell being the auctioneer. The
results of the competitions, played at the Princes course were
as follows:

The Canny Rival Challenge Cup—1st M Thomson 71 (66-18)
2nd E T McElligott 80 (93-13) 3rd J D McGrath 81 (86-5)
4th D R Wheeler 83 (93-10) and R Lindsay Rea 83 (103-20)

The O Malley Cup—1st M J Smith 71, 4 up 2nd H Lott (11)
2 up 3rd E T McElligott (13) 1 up 4th R Lindsay Rea (20)
all square

The Lett Cup—1st H Lott and D R Wheeler 1 up 2nd
J McElroy and P K Murphy all square 3rd D O Keefe and
J Grace J Doohine and L Thomson G Dawson and W McE H
McCollagh all 3 down.

Allan Perry Medal (for best scratch score)—D J McGrath 86

The Captain's Prize (for best net aggregate over 36 holes)—E T
McElligott 156 (76 and 80)

ANTRAL SEPSIS AS A CAUSE OF ILLNESS

We have received another personal experience of antral suppura-
tion, which may be computed with the one published on
October 27th (p 764). Our correspondent writes: In the winter of
1915-16 when in camp I had a bad attack of flu and in our
quarters there was about a foot of water under the huts. About
six months afterwards I was accidentally found to be suffering
from glycosuria and was under treatment for some months.
It was thought that I had a calculus in the bile duct and an
operation was advised. At that time, and for, I suppose, quite
twelve months the conjunctivae were slightly itchy. The
operation was vetoed however my condition being attributed
to chronic pancreatitis. However, as I was feeling very poorly
I determined to have the operation since life did not seem
worth living under the existing conditions. Fortunately for me
I thought I would have the antrum x-rayed and pus was found on
the right side. It was opened through the nose washed out and
kept open, it is still open and I occasionally wash it out myself.
The glycosuria disappeared in a few days and with ordinary care
in diet I have been free from sugar from that date. The jaundice
vanished in seven days. I had indulged in an excess of carbo-
hydrates and sugar there might be a trace of glycosuria but with
ordinary care and diet and without any inconvenient restric-
tions, I keep in the best of health. The condition arose when
I was about 50 years old.

POLYMASTIA

Dr R L PATERSON (Cape Province S Africa) writes: Cases of
polymastia or polymastia are not altogether uncommon, but
those in which the secondary nipples are active are I believe
sufficiently rare to warrant their being placed on record when
they do appear. In a native woman aged 44 whom I saw with
this condition each breast was well formed, and had the
usual nipple and areola about four inches below the normal
nipple and slightly medial thereto, an accessory nipple was
present on each breast. Each accessory nipple was well formed
and had around it a distinct areola. On being questioned the
patient stated that although she had not seen any milk from
these accessory nipples during lactation they excreted a watery
fluid. They never caused any trouble or inconvenience.

A COMMUNICATION with two enclosures has been received from
a correspondent in Port of Spain Trinidad who omits to sign his
name.

VACANCIES

NOTIFICATIONS of offices vacant in universities medical colleges,
and of vacant resident and other appointments at hospitals will
be found at pages 51 52, 53 56 57, and 58 of our advertisement
columns, and advertisements as to partnerships assistantships
and locum tenencies at pages 54 and 55.

A short summary of vacant posts notified to the advertisement
columns appears in the Supplement at page 219.

Remarks ON URTICARIA ITS PATHOGENESIS AND ETIOLOGY *

BY
RUPERT HALLAM, M D,
Honorary Physician in Charge of the Skin Department,
Royal Infirmary, Sheffield

THE subject of urticaria is one of considerable importance, for the complaint is not infrequently met with both in private and in hospital practice and also because of the distress it occasions its unfortunate victims. To the dermatologist it is of peculiar interest, for it exemplifies, perhaps better than any other skin complaint, the close relationship between the science of cutaneous medicine and the other branches of medicine. It serves to impress upon us the fact that a change in the skin is often the expression of some pathological process which is taking place in another part of the body, and that its elucidation and treatment require a knowledge of the latest advances in biology and physiology.

The signs and symptoms of the condition are fortunately easily recognized, although the wheals vary enormously in shape and size. Occasionally, it is true, there may be a confusion with the bullous rashes should the horny layer of the urticarial wheals be raised in the centre by an excess of serum, but this is an infrequent occurrence. On other occasions the oedema of a limb or other part of the body may be so pronounced as to earn the distinctive name "angioneurotic oedema," a term which may preferably be replaced by that of "giant urticaria."

It is convenient, perhaps, to follow the line of the majority of textbooks and divide the subject into four main groups: (1) factitious urticaria, (2) acute urticaria, (3) chronic urticaria, (4) papular urticaria of childhood, but to obtain an accurate conception it is necessary to realize that it is not a disease, but a symptom attributable to one of many causes.

Urticaria Factitia or *Dermographism*.—This peculiar response of the skin to local trauma may or may not be concomitant with urticaria vulgaris. Lewis, in his classical work on the mechanism of wheal production, states that both this form and the wheal secondary to internal causes is due to the release of a histamine-like substance from the cells of the skin. Why the person with urticaria factitia acquires this exaggerated susceptibility of the cells of the skin is not clear. The condition is met with in apparently good health. On the other hand, the incidence is higher in epileptics and alcoholics. I recently saw well-marked dermographism begin during the course of secondary syphilis.

Acute Urticaria.—It is common knowledge that this state usually follows the ingestion of some particular article of diet, and is often accompanied by more or less severe constitutional symptoms such as vomiting, diarrhoea, and a general feeling of malaise. The rash is usually profuse, and sometimes even bullous. It may involve the mucous membrane of the lips, tongue, or glottis. The latter complication, however, is rare, but cases are recorded in which tracheotomy has been necessary. Fortunately this drastic remedy may now be obviated by the hypodermic injection of adrenaline.

Chronic Urticaria.—It is this chronic, recurring stage which exercises the skill and patience of the physician, for the duration may be measured in terms of weeks and months or even years, and it may be due to an embarrassing variety of causes.

Papular Urticaria

Urticaria in the true sense of the word is not often met with in childhood, but the clinical entity known as papular urticaria, or helen urticatus, bears such a close relation-

ship to chronic urticaria that it is usually classified with it. There are, however, clinical, anatomical, and etiological distinctions between the two. The disease is only met with in childhood, and is characterized by the successive crops of small urticarial wheals, in the centre of each of which is a small papule. The wheal disappears within a few hours, but the papule remains for about a week. The causation is obscure, but there is a curious factor common to all, to which I have drawn attention in previous communications—namely, that the sufferers recover immediately they are admitted to hospital even though no treatment of any description be given. The rash returns after their discharge. Based on this experience, I have been engaged in numerous experiments during the last few years with a view of ascertaining whether there is a specific antigen responsible for the complaint, but so far have failed to detect one.

Before discussing the etiology of urticaria in detail I think it is expedient to consider briefly the present day conception of

The Histopathology of Wheal Formation

The actual microscopical changes have been accurately described by Gilchrist, Lewis, and others. The former excised a portion of the affected skin at varying intervals after wheal formation, and found a local congestion of the cutaneous vessels, an escape of serum through the capillary walls, and also definite signs of inflammatory change in the later stages. As previously mentioned, Lewis has shown that this phenomenon of wheal formation is exactly reproduced by an injection of histamine.

Change in the blood in the form of retarded coagulability and deficiency of calcium content were described by Wright,² but other observers have not always been able to confirm either change. During recent years it has been recognized that the victim of this reaction of the skin is often one who is temporarily or permanently the subject of some peculiar metabolic change, which has produced an increased susceptibility to irritants. Also, that this change is a factor in the close relationship between eczema, asthma, hay fever, and urticaria for the same individual is not infrequently a sufferer from more than one of these. The nature of this instability or sensitiveness, which is often referred to as a state of allergy, has given rise to much experimental research, but as yet the various conjectures are hypothetical. It is sufficiently clear, however, that although no organ such as the skin or the lungs shows clinical manifestation of the hypersensitive state, it must not be assumed that the particular organ is the sole site of the allergic state. It is possibly governed by highly complex changes in the cells of the individual or in the colloid stability of the blood. Allergy is found as a family disposition. The Jews are particularly subject to it, the North American Indian is not, and apparently it may be hereditary or acquired.

The Relationship to Anaphylaxis

The conception that urticaria might be a manifestation of the anaphylactic state was advanced by Wolff-Eisner³ soon after the peculiar phenomenon of anaphylaxis was first observed in animals. This theory has received considerable support, and it is generally acknowledged that, although there is a wide difference between the condition of an animal which has been re-injected after an interval of ten days with some foreign protein and a patient suffering from urticaria, yet there is a close resemblance between the two states. This is particularly evident in urticaria following serum injections, but Widall⁴ and others have shown a similarity between the alimentary type of urticaria and anaphylactic shock for in both there is a fall of blood pressure, leucopenia, moderate eosinophilia, and sometimes albuminuria. Again Bovey⁵ found that a flea does not produce a wheal after the first bite unless his host has been previously bitten by the same species of flea. A case described in *La Presse Medicale* last year also illustrates the similarity. The patient, after undergoing moderate exertion for a few minutes, not only suffered from a profuse urticarial rash, but in addition showed signs of dyspnoea, vertigo, profound cardio-vascular disturbance, and collapse.

* Made in opening a discussion in the Section of Dermatology at the Annual Meeting of the British Medical Association, Cardiff, 1928.

In examination of the blood revealed changes usually associated with anaphylactic shock.

In some cases urticaria follows the ingestion of or contact with a substance to which the patient has not been previously exposed, therefore anaphylaxis does not always serve to explain the reaction, and we have to fall back on the term "sensitization"—the inappreciable predisposition or idiosyncrasy to react to stimuli which have no effect on a normal individual. There is evidence to show that the antigen may be ingested inhaled, or absorbed through the skin, and yet produce the same results. Also that the so-called sensitiveness exists in the serum, for Prausnitz and Küstner⁷ injected the serums of hypersensitive patients into the skin of normal individuals and found that the site of the injection was temporarily sensitized to the same substance. This was confirmed by A. Walzer and M. Walzer,⁸ who noted that the serum possessed this activity for some months after it was withdrawn from the sensitized person. The susceptibility may be transmitted by a female guinea-pig to her offspring (Rosenau⁹). Another observation which has an important bearing on the treatment is that when once acquired the sensitiveness to a particular antigen appears to be followed by sensitiveness to other antigens.

May this reaction of the skin be of some protective significance? This point is raised by Memmesheimer¹⁰ in relationship to eczema, but there is little to support this hypothesis. The histology of the wheal certainly shows that cell damage takes place and therefore cell products escape into the general circulation. We know that immunity follows an attack of measles and scarlet fever, diseases in which the skin is particularly affected, but we are equally cognizant of the fact that in many other diseases involving extensive areas of skin no protection is acquired.

Etiology

Although the conception of the biological changes associated with an attack of urticaria has changed considerably in later years, it is interesting to note that the dermatologists of the middle of the last century fully recognized the diversity of the causes of the reaction. In every textbook, ancient and modern, there is a long list of both external and internal causes, and almost every observer is able to add to the list. Hebra noted that the introduction of a uterine sound produced a profuse urticarial rash in one of his patients. Crocker¹¹ quotes a case in which a ring at the front door would determine an attack. We know that it may mask a scabies infection, that it follows the ingestion of some particular food or drug. Furthermore, it may be one of the earliest signs of a grave disease such as leucæmia or diabetes, also, it may be associated with focal sepsis. The latter coincidence has been so frequently demonstrated in recent years that it must be accepted. My own view is that focal sepsis plays a far greater role in the causation of chronic urticaria than food protein, and that in the past it has been assumed too readily that urticaria is the outward manifestation of food poisons.

As the chance of successful treatment largely depends on the detection of the cause, it is essential that a case of urticaria should be approached with the greatest circumspection, and also with the knowledge that there is no specific remedy. A detailed history will be required, the skin will need careful inspection to exclude the possibility of local irritants. Protein sensitization tests must be considered, although these have not given the assistance that was anticipated from them. Each system will require examination, for none is above suspicion. The key to the mystery may be the examination of the blood. In a recent article F. R. Monaghan¹² claims that disease of the biliary tract was an etiological factor in 50 per cent of his cases. A high incidence of urticaria has been described in patients with syphilis, and I have met with this coincidence on several occasions, but antispasmodic treatment has not prevented the recurrence of the wheals.

It is sufficiently obvious that there are innumerable possibilities to be considered, and that the physician who successfully detects the offending abnormality has good reason to congratulate himself. That trauma plays an

important part as an exciting cause was demonstrated as long ago as 1888 by Jaquet, who found that when a limb of a patient suffering from generalized urticaria was protected the wheals did not arise on the skin of that limb.

Desensitization

Should the offending antigen be detected, desensitization may be attempted by giving minute, increasing doses until tolerance is established. On the assumption that urticaria is a manifestation of the anaphylactic state French dermatologists have recently advocated the ingestion of 0.5 gram of peptone one hour before each meal.

Empirical Remedies

Calcium salts have had a long innings, but in my experience the results have been singularly disappointing, and in my opinion confidence in the supposed virtues of this drug have many times been responsible for an inadequate examination of patients. Urticaria has been noted in hypothyroidism, therefore thyroid extract has recently been prescribed as a remedy, one author, indeed, proclaims it as a specific. I do not go so far with him, but believe, in the unhappy event of the actual cause not being ascertained, that thyroid extract is worthy of a trial. Popular urticaria is influenced neither by dieting nor drugs, but, as already mentioned, the patient obtains a respite if he be removed from his own environment. True, the rash often recurs when the patient returns home, but I have noted a permanent benefit in a number of instances, and recommend a trial when practicable.

BIOCHEMICAL INVESTIGATIONS IN ALLERGIC CONDITIONS*

BY

H. W. BARBER, M.A., M.B., F.R.C.P.,

AND

G. H. ORIEL, M.A., M.D.

Our communication is concerned almost entirely with certain biochemical investigations carried out by one of us (G. H. O.) in what may be termed allergic conditions. The word "allergy," in the sense originally employed by von Pirquet, has a narrower significance than others have given to it, for, as Danier points out, although including all forms of acquired hypersensitiveness, it excludes inborn hypersensitiveness or idiosyncrasy. We do not, however, consider this distinction of practical importance, or, in fact, valid, and with Doerr, Zinsser, Wells, Duko, and others, we employ the term to indicate almost all forms of hypersensitiveness.

Allergy is beyond question the most important biological and medical problem that exists or ever has existed, for it represents the pathology of the reaction of man and the lower animals to their environment—to the air they breathe, the physical agents, such as light, heat, and cold, to which they are exposed, the food they eat, and the various parasitic organisms which may invade them.

Moreover, in our opinion the discussions that have arisen as to whether or not the so-called allergic conditions, such as hay fever, asthma, and urticaria, should be termed anaphylactic reactions, or whether they differ essentially from true anaphylaxis as produced in animals experimentally, or as it may occur accidentally in man, are profitless. The important fact is that many of the

* Read in a discussion on urticaria in the Section of Dermatology of the Annual Meeting of the British Medical Association, Cardiff 1928.

symptoms to which sensitized persons are liable are identical with those seen in animals suffering from anaphylactic shock—for example, contraction of the pilo-motor muscles with erection of the hair follicles, sneezing and coughing, pruritus, urticaria, respiratory distress consequent upon the contraction of the smooth muscle of the bronchioles, and oedema of the bronchial mucous membrane, diarrhoea, diuresis, and epileptiform convulsions.

The following list includes the majority of conditions which are certainly, or in some instances probably, of allergic origin.

Cutaneous—Urticaria, true infantile eczema, certain forms of eczema occurring after infancy, certain forms of pruritus, prurigo of the Besnier type, prurigo of the Hebra type, prurigo of the simple type, prurigo nodularis, urticaria papulosa (lichen urticatus, strophulus), ichthyosis light sensitization of the adult type, dermatitis herpetiformis (probably).

Subcutaneous—Angioneurotic oedema.

Respiratory Tract—Paroxysmal rhinitis, of which hay fever is one of the commonest examples, asthma.

Gastro-intestinal Tract—Certain forms of vomiting and diarrhoea.

Nervous System—Migraine, epilepsy (probably).

Articular System—Paroxysmal hydrarthrosis.

This list, although it may appear formidable, is doubtless incomplete. Freeman¹ includes functional albuminuria, and tentatively dermatographia, paroxysmal colitis, and white leg.

The literature of allergic conditions, from both the clinical and the pathological standpoint, is so vast that we have made no attempt to review it. We shall merely summarize our own observations and refer to a few communications of other workers that bear upon them.

It may be of interest to record how we came to investigate the biochemistry of allergic manifestations. It seems clear that in cases of what may be called the ichthyosis-asthma-hay fever-eczema-prurigo-urticaria-migraine syndrome, in which there is almost invariably a strong family history of one or other of these various manifestations, there must be some inborn metabolic kink—comparable to Garrod's "inborn errors of metabolism"—which predisposes the affected person to becoming sensitized to various proteins.

The inherited "sensitizability" of Cooke and van der Veer must have some metabolic explanation, and in persons, previously normal, who develop the allergic state it was thought the same metabolic error would be found. Now the view has long been held, not only by certain clinicians but also by laboratory workers, that both in experimental anaphylaxis and in allergic conditions, such as asthma and urticaria, the essential factor is what may be vaguely termed "hepatic insufficiency." One need only refer in this connexion to the writings of Widal and his co-workers, of Manwaring, and, from the clinical standpoint, to the views of Moncorge and others, on the pathogenesis of asthma.

One of us (G. H. O.), working on oedema from the biochemical point of view, had discovered a phenomenon in the urine, which may be termed the "ether reaction," in certain cases of cardiac failure. This reaction will be described and discussed later. On testing the urine of normal controls, he found that one of his laboratory assistants gave a strongly positive test, and on questioning the man, he learnt that he was healthy except that he suffered from urticaria. It was then found that other urticarial subjects also gave positive tests. The question therefore was: What is the connexion between cardiac failure with oedema and urticaria? It occurred to us that the most probable explanation was either that in both conditions there is some degree of hepatic insufficiency, or that some factor concerned with the production of tissue oedema was common to both. It was then decided to test the urines of persons with allergic symptoms other than urticaria, and positive reactions were at once found in cases of prurigo of the Besnier type, with or without asthma, in asthma without cutaneous symptoms, in urticaria papulosa, in angioneurotic oedema, in certain cases of prurigo of the simple type, in infantile eczema and in

migraine. Numerous normal controls were, of course, also tested. It was further found that the reaction was strongly positive in obstructive jaundice, in cirrhosis of the liver and in cases of toxic jaundice—for example, from salvarsan or acute infections—thus lending, perhaps, additional support to the view that the reaction was an indication of hepatic insufficiency.

Assuming, therefore, that these allergic conditions were, at any rate in some cases, associated with functional hepatic insufficiency, and that such insufficiency concerned protein metabolism (cf. the proteoexcretory function of the liver of Widal) the next step was to estimate the amino-acid content of the blood in patients with allergic manifestations and in normal controls.

The method used was that of Folin, as described in *Recent Advances in Medicine* by Beaumont and Dodds.

AMINO-ACID CONTENT OF THE BLOOD

It would appear from our own investigations and those of others that the average normal figure for the amino-acid content of the blood is from 4.0 to 6.5 mg. per 100 c.c., the latter figure being distinctly a "high normal." In order to determine the effect of a meal containing plenty of protein, what may be called "protein-tolerance tests" were performed in normal subjects and in those with allergic symptoms. A determination of the amino-acid content of the blood was made before breakfast or several hours after a meal, and a mixed meal containing various proteins was then given, and estimations were made one, two, and three hours afterwards—for example:

G. H. O. normal subject before breakfast 3.7 mg. per 100 c.c. one hour after breakfast 4.7 mg., which figure remained constant two and three hours afterwards.

N. normal subject 5.0 mg. before a meal 5.8 mg. afterward.

K. R. normal 4.0 mg. before 5.6 mg. afterwards.

A case of dermatographism and urticaria 5.0 mg. before a meal one hour afterwards 5.5 mg. two hours afterwards 6.2 mg. when there was slight urticaria three hours afterwards 5.8 mg. when the urticaria had disappeared.

W., a case of asthma and prurigo fasting 7.0 mg. one hour after meal 7.2 mg. two hours after 7.4 mg. three hours after 7.2. It will thus be seen that there is a slight rise in the amino-acid content of the blood after a protein meal both in normal persons and in others.

A very large number of estimations have been carried out in patients with allergic manifestations, the majority of cases investigated being classical examples of the ichthyosis-asthma-hay fever-eczema-prurigo-urticaria-migraine syndrome, in a considerable proportion of which more than one of these various symptoms were combined. In this group, which for brevity's sake we will term the asthma-prurigo group, a high amino-acid content of the blood was found to be constant in untreated cases but it is necessary to make this reservation—that the patient, as a rule, were seen when one or other of their symptoms, usually the prurigo, was active. After dietetic and other treatment, and probably also during the remissions, that so often and so inexplicably occur in these patients, normal figures may be obtained. For example:

W. was a typical example of the group. He gave a family history of asthma and migraine, suffered himself from infantile eczema which was later followed by asthma and prurigo of the Besnier type with lichenification involving chiefly the antecubital fossae, the popliteal spaces, the dorsal surfaces of the wrists and hands, the circumoral and frontal regions. He is an ichthyotic. When seen early in December 1927 he was having moderately severe asthmatic attacks about three times a week and nocturnal exacerbations of itching. His lips were bluish in colour and rhonchi were audible in the chest. The blood drawn in the afternoon—a quiescent period—gave an amino-acid content of 7.0 mg. per 100 c.c. He was ordered a vegetarian diet except that he was told to eat some lightly cooked liver if possible daily and given aspirin to take three times daily. In a fortnight he returned transformed in appearance. He was entirely free from asthma, had little or no itching and his lips were now pink. The amino-acid figure was 5.8—that is, normal. Treatment was suspended, he returned in January having kept very well except for slight asthma and itching at night time. His amino-acid figure then was 7.0. Early in March he came again having had a severe relapse following a gastro-intestinal upset. He was having asthma every night with intense ichthyosis, his lips had become blue again and his chest was full of rhonchi. The amino-acid figure was 9.3. Treatment was again ordered, and he returned in a fortnight much improved. The amino-acid content had fallen to 7.0.

It is our impression that in cases of Besnier's prurigo, with or without asthma, the amino-acid content of the

blood tends to be high even during periods of comparative freedom from itching. Thus

S. C., a man aged 42, family history of eczema, ichthyosis on the father's side. Had infantile eczema. Asthma began at the age of 2 years. Asthma and irritation of the skin were provoked by contact with horses and cows, also asthma with catarrhal infections. Severe urticaria and angioneurotic oedema from Brazil nut which once nearly caused death from oedema of the glottis when taken accidentally. Has ichthyosis and prurigo of the Besnier type in antecubital fossae, popliteal spaces, wrists, and face. Cutaneous tests: Horse +++ cattle +, dog +, sheep +, Brazil nut +++ During a period of almost complete absence of symptoms nevertheless had an amino-acid figure of 9.8.

V., a little boy with Besnier's prurigo, formerly infantile eczema and asthma, at a time when the prurigo was slight had an amino-acid figure of 8.2.

P. B., a little girl with asthma, hay fever, horse sensitiveness, eczema, prurigo and urticaria. Seen during one of her best periods when she was having no asthma and only slight itching, amino-acid 9.3.

Of forty-one patients belonging to this group, in nearly all of whom there was a combination of asthma or hay fever with prurigo of the Besnier type, and several of whom were ichthyotics, the average figure for the amino-acid content of the blood was 8.8. The highest figure in this series was 10.7, the lowest 7.0, but examinations made in a few asthmatic patients during an actual attack gave much higher readings—for example, 17.5 in one case, 18.6 in another. These figures have not been included in the above series.

In simple cases of urticaria and of asthma without prurigo it would appear that in the intervals between the attacks the amino-acid figure may be normal, or nearly so, but it rises rapidly during the paroxysms. Thus the asthmatic who in an attack gave the above figure of 18.6 gave in a quiescent period only 6.8, and the patient with 17.5 in the attack at another examination gave 8.0. One case of urticaria gave 6.4, rising during an attack to 11.8, another 5.0, rising to 7.4 and 9.3. Some of our urticarial patients with nocturnal attacks have given figures well within normal limits during the daytime; in others, however, they have been raised even at times when no eruption was present. A patient with angioneurotic oedema gave 6.0 in an interval between attacks, rising to 8.2 during one.

To sum up, the conclusions at which we have arrived from investigations made in a large number of patients are as follows:

1. During the acute paroxysms of allergic manifestations the amino-acid content of the blood is very markedly raised.

2. In cases of prurigo of the Besnier type, in which asthma, hay fever, and ichthyosis were often also present, high figures were usually obtained even during periods of comparative freedom from symptoms. The figure rose still higher during the paroxysms of itching.

3. In cases of simple urticaria or of angioneurotic oedema, and of asthma without prurigo, the figure may be normal or nearly so in the quiescent stage, but is constantly raised, sometimes to an extraordinary extent, during the attacks.

A raised amino-acid content of the blood has also been found in cases of light-sensitization of the adult type, in four cases of dermatitis herpetiformis, in some cases of simple prurigo occurring for the first time in adult life, in prurigo nodularis (three cases), in certain cases of eczema of the "gouty" type associated with a high blood pressure, in a case of dermatitis exfoliativa of unknown cause, in cases of salvarsan poisoning with jaundice, in one patient with cirrhosis of the liver, and in a case of intermittent hydrarthrosis associated with psoriasis. On the other hand, normal figures have been obtained in uncomplicated psoriasis, in one case of cirrhosis of the liver, in one case of toxic jaundice following tonsillectomy, in a case of sarcoid, in one of alopecia areata, and in a case of generalized eczematous dermatitis apparently due to septic absorption. In healthy normal subjects the figures are remarkably constant.

In experimental anaphylactic shock Hisanobu found a rise in the blood of total non-protein nitrogen and of amino-nitrogen.

With regard to the other non-protein nitrogenous substances—for example, urea, uric acid, and creatinine—we have not as yet estimated them in the blood in a sufficient

number of cases to enable us to draw any definite conclusions, but it would appear that during the acute paroxysms their quantity is raised. At all events, they are excreted in increased amounts in the urine at and during the period immediately following the paroxysms, and the output of creatinine would seem to be particularly high in cases of urticaria. Such an increase of non-protein nitrogen excretion has also been observed by Longcope and Rackemann to follow attacks of acute urticaria.

As to the significance of a raised amino-acid content of the blood we can say nothing. It is possible that it may be at any rate partly accounted for by the presence in the blood of toxic amines, of the histamine type, which are known to produce symptoms comparable to anaphylactic shock, and the various allergic manifestations. On the other hand, it may merely be an indication of the disturbance of endogenous protein metabolism that obtains in anaphylactic shock, and in the proteose intoxication which, as Whipple and others have shown, occurs in experimental intestinal obstruction, and in which the non-protein nitrogen in the blood is greatly raised. That the endogenous protein metabolism is excessive in the acute stage of allergic states is shown by the increased creatinine excretion that follows them.

CHLORIDES

In the early period of our work the importance of the chloride content of the blood and of the urinary excretion of chloride was not realized. Of late, however, one of us (G. H. G.) has investigated cases of various diseases from this point of view, with significant results.

In serum disease von Piquet and Schick showed that there was a relative increase in weight which they considered due to retention of fluid. Rackemann, Longcope, and Peters demonstrated that there is, during the active stage of serum disease, a marked but transient retention of chlorides and water, associated sometimes with a slight albuminuria and cylindruria, and occasionally with an impairment of the excretion of phenolsulphophthalein by the kidneys. They stated that in patients with oedema and a gain in weight during serum sickness the plasma chlorides were below normal. Rackemann and Longcope also investigated six cases of urticaria both during and after attacks. In one patient sensitive to beef and sheep protein the attack of urticaria was associated with a rise in blood urea, a decrease in the phthalein output, diminished excretion of urine, and almost complete suppression of chloride and nitrogen excretion. During the period immediately after recovery the nitrogen and chloride excretions were excessive, and the blood urea, the phthalein output, and the water exchange returned to normal. During this period there was a loss of almost 8 lb in weight. These results, as will be seen, correspond almost exactly with our own findings in allergic diseases.

In infantile eczema Lust and Lederer found at times a considerable increase in the water content of the blood as compared with normal infants, and wide and rapidly occurring fluctuations of the water content were characteristic. These fluctuations appeared to depend on alterations in the metabolism of mineral salts. Freund found that eczematous infants showed a much greater retention of chloride than non-eczematous infants on the same diet. This retention of chloride was coincident with a rapid gain in weight due to a simultaneous water retention. Meyer found that if eczematous infants were underfed there was a much greater excretion of mineral salts than in normal infants on the same diet.

In considering the chloride content of the blood a distinction must be drawn between the serum content and the whole blood content. The chloride content of a given volume of serum is greater than that of the same volume of whole blood, showing that normally the serum chloride exceeds that in the corpuscles. The normal readings are fairly constant: a series of estimations in normal controls gave figures varying from 570 to 585 mg per 100 c.c. of serum, and 454 to 495 mg per 100 c.c. of whole blood. These may probably be taken to represent the normal limits. The chloride content is estimated as the chlorine ion, and the result expressed in terms of sodium chloride, although the actual combination of the chlorine ion varies in the serum.

and the red cell, it is probably present as sodium chloride in the serum and potassium chloride in the red cell

Now it would appear that in acute and chronic allergic manifestations the whole blood chlorides are markedly diminished, whereas the serum chlorides may remain about normal—that is, there is a reduction of the corpuscle content of chloride. As with the increase of the blood amino-acid content, we have found that this reduction of whole blood chloride is most constantly found in the asthma-prurigo group, and, like it, varies with the exacerbation or remission of the symptoms. In simple urticaria the chloride reduction takes place, like the increase in blood amino-acid, during the attacks, and usually returns to normal in the intervals. Thus

Disease	Amino-acid Content of Blood Mg per 100 c cm	Serum NaCl Mg per 100 c cm	Whole Blood NaCl Mg per 100 c cm
Normal	4.0-6.5	570-585	454-495
1. Asthma, ichthyosis prurigo	7.0-9.3	577	346
2. " " " "	7.0-7.7	561	363
3. " " " "	7.0	627	396
4. " " " "	7.0	561	322
5. " " " "	7.0	610	380
6. " " " "	7.0		380
7. " " " "	8.7		305
8. " " " "	8.7		430
9. " " " "	7.0		363
10. Asthma, ichthyosis prurigo urticaria	10.0		412
11. Angioneurotic oedema urticaria (quiescent stage)	7.0		396
12. Asthma, ichthyosis prurigo urticaria	9.3		412
13. Asthma	7.0	577	363

One case of severe prurigo of the Besnier type associated with occasional attacks of asthma was investigated at various times

On April 24th 1928 after having been for some time on a vegetarian diet the patient was fairly free from itching. Amino-acid 5.4 mg per 100 c cm serum NaCl 577 mg per 100 c cm whole blood NaCl 396 mg per 100 c cm. Given sal volatile potassium bicarbonate, and urea. On May 1st was much better. Serum NaCl 610 mg per 100 c cm whole blood NaCl 430 mg per 100 c cm. On May 7th patient had a relapse with severe itching and asthma following a catarrhal infection with some pyrexia. Amino-acid 7.0 mg per 100 c cm serum NaCl 561 mg per 100 c cm whole blood NaCl 363 mg per 100 c cm. On May 13th the asthma had gone but there was still some itching. Amino-acid 7.7 mg per 100 c cm whole blood NaCl 396 mg per 100 c cm

A case of angioneurotic oedema gave the following figures

	Before Attack.	During Attack.
Amino-acid	5.8 mg per 100 c cm	8.2 mg. per 100 c cm
NaCl (whole blood) ..	480 " "	396 " "
NaCl (serum)	580 " "	577 " "

THE URINE

A study of the urine has proved of very great interest and importance in allergic states, and it is no exaggeration to say that not only can we now deduce from a given specimen, taken from a person with allergic symptoms, whether it was passed at the onset or during the paroxysm or in the period following it, but we can also predict the urinary findings according to the condition of the patient at a given time

There are two phenomena which we believe to be almost if not quite constant in persons with allergic symptoms at certain times during the periods of active manifestations—namely the ether reaction, already referred to and the deposition of urates in the urine on cooling. These will be discussed later

Before considering the urinary findings in detail it is advisable to summarize what we have found to occur in the cycle of events that takes place in all the acute allergic states so far investigated—for example, an attack of asthma, urticaria, angioneurotic oedema, or migraine, and in the paroxysms of itching that occur periodically in prurigo and infantile eczema. In the period just preceding and during the paroxysms we find

Blood

- 1 The amino-acid content rises
- 2 The uric acid and creatinine are also apparently increased
- 3 The chloride content of the whole blood—chiefly of the corpuscles—falls

Urine

- 1 Free acidity rises
- 2 Urates are often deposited when the urine cools
- 3 Diminished water excretion, so that the specific gravity is usually high
- 4 Retention of chlorides
- 5 Ether reaction strongly positive
- 6 Ammonia excretion rises and the ratio of free acid to ammonia is altered
- 7 Excretion of amino-acid, creatinine and uric acid begins to rise

In the period following the subsidence of the paroxysm we find

Blood

- 1 The amino-acid content falls again
- 2 The uric acid and creatinine also diminish
- 3 The chloride content of the whole blood rises again

Urine

- 1 The free acidity rapidly and progressively falls, and the urine tends to become neutral and finally alkaline sometimes strongly so
- 2 Increased excretion of water, so that the volume is raised and the specific gravity falls (post-paroxysmal diuresis)
- 3 The excretion of chlorides is increased
- 4 The ether reaction diminishes and may entirely disappear
- 5 The excretion of ammonia begins to fall but it is so slow that the ratio of free acid to ammonia is still further altered
- 6 Excretion of amino-acid, creatinine and uric acid gradually falls

The Precipitation of Urates

The precipitation of urates in the urine on cooling is a phenomenon that has not, in our opinion, received sufficient attention from clinicians. It is usually taught that such a precipitation when the urine cools depends on (1) the concentration, (2) acidity. As a matter of fact these factors are of relatively minor importance. We have seen a heavy deposit of urates in a urine with a quite low free acidity and a specific gravity of only 1012. The following remarks are taken almost *in extenso* from an article on renal calculi by Jacob Rosenbloom in *Endocrinology and Metabolism* (D Appleton and Co., New York and London, 1924, vol 4, pp 465-467)

Temperature, as is well known, has a great influence on the solubility of acid sodium urate. It may often be observed that a precipitate which disappears on boiling the urine does not reappear on cooling, and that the urine remains clear for hours or even days. Some change must therefore have taken place in the urine by heating. Decomposition of uric acid is not in question, decrease of acidity from the small loss of CO₂ cannot account for the change. One can even make the urine more strongly acid after heating without hastening the formation of a precipitate. This phenomenon of change in solubility may be found at times in urines which give a dense uric acid precipitate on acidification. If one adds the same amount of acid to the heated urine the precipitation may fail or come later

It can be shown that, by boiling a change in the solubility state of the colloid is produced. Lichtwitz examined fifty-seven such urines for their colloid conditions. The gold count was made before and after boiling and the time noted that the sediment remained in solution. The gold count increased from two to ten times—that is the uric colloids were in a state of precipitation in these urines, and became reversible through boiling as gelatin by warming goes into a finer separation. In eighteen urines that precipitated on cooling the gold count was the same before as after boiling—that is, the colloid which these urines contained was in an irreversible precipitation state. Such urines may be without defence action for colloidal gold solutions. Lichtwitz observed a patient who passed urine for four weeks without a gold count with abundant uric acid sediment only on one day was the urine clear and acted protectively on the gold solution.

These observations show that the solubility of the uric acid and its salts depends on the colloid state of the urine. The concentration is of subsidiary importance, for precipitation may occur with quite normal amounts, while abnormal amounts may remain in solution. Other conditions being the same, a sediment occurs naturally more readily in concentrated urine. The reaction is of significance merely in so far that precipitation only occurs in acid urines. If occasionally the reaction is neutral, it is due to the fact that in crystallization hydrogen ions have left the solution and thereby reduced its acidity. At any rate, in very strongly acid urines the uric acid may remain dissolved.

The dominant factor for the solubility is the state of the urino colloids. It may be here remarked that, since the precipitation of urates does not depend on the uric acid itself, such precipitation does not in any way indicate the "uric acid diathesis." Brugsch and Schittenhelm have pointed out that whereas true gout is extremely rare in childhood, uric acid stone is most frequent, and the majority of cases of urate stone diathesis occur without true gout.

Now although the precipitation of urates may be found in the urines of apparently normal healthy people, it is, in our experience, comparatively rare, and we believe that, apart, perhaps, from its occurrence after excessive sweating, it is an indication, even in persons organically sound, of at any rate a temporary functional metabolic disturbance. One of us (H. W. B.) makes a rule to examine an early morning specimen of urine of nearly every patient he sees in private practice, and urates are more commonly deposited in the night or early morning urine than at other times, nevertheless, except in patients with allergic symptoms, it is rare to see a specimen with uratic sediment. Even in patients with acute seborrhoeic manifestations, in whom the urine is usually excessively acid, such sediment is very uncommon.

In allergic diseases, however, it is so frequently met with as to be almost constant at some period in the twenty-four hours, at least during the phase of active manifestations. In infantile eczema, urticaria, and in the asthma-prurigo syndrome, for example, an inquiry as to whether a reddish sediment has been noticed in the urine on cooling will almost invariably be met with an affirmative reply.

It would seem, therefore, that in allergic diseases there is an alteration in the colloidal state of the urine which predisposes to the deposition of urates, and one naturally asks whether this phenomenon is not a reflexion in the urine of the *crise hémoclasique*, or *colloïde clasique* in the blood.

The Ether Reaction

This reaction, as has been said, was first observed by one of us (G. H. O.) in cases of cardiac failure with oedema. The test is performed as follows. To a few cubic centimetres of urine are added first a little of a 25 per cent solution of sulphuric acid, and then sufficient ether to form a layer above the urine about half an inch in depth. The mixture is then thoroughly shaken, with the thumb over the mouth of the test tube, and allowed to stand. The layer of ether becomes frothy, but, if the reaction be positive, the froth in its lower part becomes viscous and opaque, like melted wax, after ten minutes or so. In strongly positive tests the tube of urine can then be inverted without spilling. The degree of positiveness is measured by the depth of the waxy scum beneath the superficial froth, and we would here emphasize that the test is one of degree only, because a slight reaction—that is, the formation of a narrow band of opaque scum—is frequently found in apparently normal people. For this reason we do not wish to exaggerate the importance of this reaction, nevertheless it is one of great interest, and deserves further study.

Microscopically the viscid scum is found to consist of finely divided globules. When the ether is evaporated there remains a little urine. Chemical analysis has thrown no light on the phenomenon, the various substances identified in the scum being normal constituents of urine, such as hippuric acid. Presumably, therefore, the reaction merely depends on reduction of surface tension. This is supported,

perhaps, by the fact that it is well seen in jaundiced urines.

As far as our observations go the reaction is always strongly positive during the acute phase of allergic manifestations, but may disappear during the period of quiescence. We have, for example, found it very marked during the acute eruptive stage of urticaria and urticaria papulosa, though sometimes practically absent between the outbreaks. In migraine—and Dr Moroland McCrea has confirmed this—it is positive during the attacks, but may be negative at other times. In infantile eczema and the asthma-prurigo syndrome, it may be well marked in practically every specimen of urine examined, but is always most intense during the paroxysms of itching.

We have also found it in serum sickness, in hepatic disease, in acute febrile infections such as pneumonia, and in certain cases of active tuberculosis, and we have seen it strongly positive in some cases of acute toxic eruptions from food poisoning, and in generalized eczemas due apparently to sensitization to external irritants.

It would seem likely that there is a connexion between this reaction and the deposition of urates, both being probably dependent on an alteration in the colloid state of the urine, and it may be of significance that Kropczewski and Yakiam have shown that sodium oleate suppresses anaphylactic shock in sensitized animals, as also do saponin, sodium taurocholate, and sodium glycocholate, presumably owing to their power of reducing surface tension in the plasma.

Urinary Acidity and Concentration

The acidity of the urine, as already remarked in the summary of what may be called the allergic cycle, varies according to the particular phase of the cycle. In the period preceding an attack the free acidity is, if anything, raised, but as the attack proceeds and diminishes the acidity falls, and the urine tends to become neutral and sometimes strongly alkaline, with a deposit of phosphates. During the acid stage the urine is usually concentrated, there being a diminished water excretion, and very commonly deposits urates on cooling, although, as has been remarked, uratic deposits may occur in urines of only moderate acidity and comparatively low specific gravity. During the alkaline stage it is dilute, there being a diuresis, which has long been noted clinically, for example, after asthmatic attacks. A patient may, in fact, during the same period of twenty-four hours, at one time pass a strongly acid concentrated urine with a deposit of urates and at another a highly alkaline dilute urine with a deposit of phosphates.

Ammonia.—The ammonia excretion is one of the most remarkable features of the allergic state, because it does not correspond to the degree of acidity. The normal ratio between the free acid and the ammonia excretion varies from 1.06 to 1.15 according to Davis and Rixon,² 1.1 being probably the normal average, according to our own investigations.

In persons with allergic symptoms the ammonia excretion is raised, often to an extraordinary extent, and the ratio is found to be abnormal at the period of and following the paroxysm. For example, a lady with asthma and hemified eczema of the hands gave the following figures:

Time	Free Acid	Ammonia	Ratio	Volume	Volume per Hour
4.15 p.m.	38.4	21.6	1.15	120 c.c.m.	
8.0 p.m.	50.4	17.0	1.16	180 c.c.m.	45 c.c.m.
2.0 a.m.	29.4	13.0	1.30	210 c.c.m.	35 c.c.m.
5.0 a.m.	14.4	9.0	1.40	180 c.c.m.	60 c.c.m.
6.0 a.m.	8.0	9.0	1.70	150 c.c.m.	180 c.c.m.
7.0 a.m.	—8	34.0		210 c.c.m.	
Total	132.5	58.6	1.26	1,050 c.c.m.	

The asthmatic attack was nocturnal, and it will be observed that in the latter half of the night the free acid progressively diminishes until at 7 a.m. the urine is alkaline whereas the ammonia excretion, so to speak,

lags behind, and at 6.30 a.m. a ratio of 1.70 is obtained. The diuresis accompanying the alkaline stage is well shown.

A boy of 18 with asthma and prurigo gave the following figures:

Day of No Attack

Time	Free Acid	Ammonia	Ratio	Volume	Volume per Hour
11.20 a.m.	24.0	91.8	1.20	150 c.cm.	
5.15 p.m.	45.0	122.4	1.16	150 c.cm.	25 c.cm.
7.10 p.m.	23.0	67.3	1.18	90 c.cm.	45 c.cm.
5.45 a.m.	114.0	346.0	1.14	600 c.cm.	60 c.cm.
Total	235.0	627.5	1.15	930 c.cm.	

Day of Attack

Time	Free Acid	Ammonia	Ratio	Volume	Volume per Hour
1.20 p.m.	16.0	122.4	1.45	90 c.cm.	
4.10 p.m.	7.0	65.0	1.54	90 c.cm.	30 c.cm.
7.0 p.m.	12.0	38.0	1.20	90 c.cm.	30 c.cm.
4.30 a.m.	79.2	314.0	1.30	650 c.cm.	66 c.cm.
9.15 a.m.	27.0	128.0	1.28	270 c.cm.	
Total	141	667	1.27	1,200 c.cm.	

The following figures were recorded in a case of angioneurotic oedema:

Time	Free Acid	Ammonia	Ratio	Volume	Volume per Hour
7.0 p.m.	52.8	157.0	1.17	300 c.cm.	
Adrenaline 8.0 p.m.					
6.0 a.m.	115.2	440.0	1.23	720 c.cm.	65 c.cm.
10.45 a.m.	neutral	148.0		330 c.cm.	66 c.cm.
1.45 p.m.	neutral	31.0		90 c.cm.	30 c.cm.
4.0 p.m.	-26.4	67.0		660 c.cm.	330 c.cm.
Total	142	894	1.36	2,130 c.cm.	

It will be noted in this case that the attack of angioneurotic oedema was already present when the investigations were begun, and that adrenaline was administered after the first specimen of urine was examined. The figures show the gradual diminution of acidity with ultimate alkalinity, although the ammonia excretion remains high, and the very marked diuresis. Moreover, it will be seen that this progression towards the alkaline side is common to both asthma and angioneurotic oedema, and cannot be explained merely by the hyperpnoea that occurs in asthma.

Urea, Creatinine, and Uric Acid.—It will thus be seen that the ammonia excretion is raised in association with the paroxysms; the other non-protein nitrogenous substances—namely, urea, creatinine, and uric acid—are also correspondingly increased.

Chlorides.—The diminution of the chloride content of the red corpuscles has already been noted. Examination of specimens of urine taken at different times during the twenty-four hours in a patient with active allergic symptoms has shown repeatedly that during the active stage there is retention of chlorides, with a consequent low excretion of them in the urine, whereas after the paroxysm the excretion rises. This chloride retention has been shown to occur by Rackemann, Longcope, and Peters in serum sickness, and by Longcope and Rackemann in cases of urticaria. It is a well-known phenomenon in pneumonia and in other acute infections, such as scarlatina and typhoid fever. Kartavitschew and Pokorwy, and d'Urbach have

also emphasized its occurrence in pemphigus vulgaris and in dermatitis herpetiformis. In all probability it is a protective mechanism, and the experiments of Richet and others on the prevention of anaphylactic shock in animals by the previous injection of sodium chloride support this view.

CONCLUSIONS

The points we would emphasize in the foregoing summary of some of our investigations into the metabolism of allergic conditions are as follows:

1. Certain phenomena have been demonstrated to occur with remarkable constancy in various manifestations of the allergic state, some of these have already been described in experimental anaphylaxis and in serum sickness, which is generally admitted to be truly anaphylactic in origin.

2. In the allergic state, whether it be intermittent, as in certain cases of urticaria, angioneurotic oedema, and asthma, or whether it be more or less chronic, with periodical exacerbations or remissions, as in Besnier's prurigo and infantile eczema, there can be recognized a definite cycle of events corresponding to the pre-paroxysmal stage, the actual paroxysm, and the post-paroxysmal stage. In this cycle the most striking features are:

- (a) The rise in the amino-acid content of the blood.
- (b) The rise in the ammonia excretion out of all proportion to the excretion of acid in the urine.
- (c) The lowering of the corpuscle content of chloride and the retention of chloride during the paroxysm with its subsequent excretion as in pneumonia and other acute infections.
- (d) The deposition of urates in the pre-paroxysmal or paroxysmal stage.
- (e) The ether reaction during the periods of active manifestations.
- (f) The diuresis with decreasing acidity and sometimes marked alkalinity of the urine in the post-paroxysmal stage.

3. The deposition of urates and the ether reaction in the urine indicate an alteration in its colloid state, comparable probably to the colloidal change that is held to occur in the blood during anaphylactic shock.

4. It is probable that the increased ammonia excretion and the retention of chlorides are protective mechanisms.

HAEMOGLOBINURIA AND URTICARIA ARISING FROM COLD

A NOTE ON THE PRESENCE OF A DEHYDOLYSIS *

BY

KENNETH E. HARRIS,† THOMAS LEWIS,
AND JANET M. VAUGHAN

(From University College Hospital Medical School)

OBSERVATIONS upon three patients, the first suffering from paroxysmal haemoglobinuria and urticaria, the second from simple cold urticaria, and the third from uncomplicated paroxysmal haemoglobinuria are here recorded. The investigations are still incomplete: the present note is therefore a preliminary account only.

CASE I

H.D. is a slightly anaemic girl aged 11 years, for about two years she has passed dark urine after exposure to cold such as going out in winter or washing herself in cold water. Apart from a positive Wassermann reaction given both by herself and by her mother there is no evidence of congenital syphilis. When tested by bathing in cold water to demonstrate the haemoglobinuria extensive whealing of the skin developed. On further questioning she has given a history of nettlerash appearing after being out in the cold on exposed areas of the body and mainly affecting the hands and the face.

The case is typical of paroxysmal haemoglobinuria occurring in response to exposure to cold. This condition has been proved by Donath and Landsteiner, Eassey, and others to be due to the presence in the patient's blood of a haemolysin, which unites with red

* Work undertaken on behalf of the Medical Research Council.
† Assistant on the Medical Unit.

blood cells only at relatively low temperatures, but requires subsequent warming to body temperature to allow the necessary union with complement and consequent haemolysis. This phenomenon has been demonstrated by repeated experiments on the blood of our patient *in vitro*. The skin reaction to cold in this patient is of the usual form seen in other skin injuries—namely, the triple response, cold of the degree here used produces no such response in normal persons. In previous publications from this laboratory,^{3, 4} a great deal of evidence has been brought forward to show that this triple response—namely, local reddening, increased permeability leading to whealing, and a reflex arteriolar flare—is due to the liberation of a histamine-like substance already present in the skin cells. The reaction occurs in this patient as a sequel to cold applications, temperatures of from 0° to 19° C being effective in producing whealing, at 0° C cooling for only half a minute is sufficient. The reaction is purely local.

The response of the skin to cooling is due to the presence of a dermolysin in the patient's blood. The skin of other subjects is rendered similarly sensitive to cold by the intradermic injection of this patient's serum.

The conditions under which the dermolysin and the haemolysin act are similar. Thus, cooling followed by warming is essential in both instances, and very prolonged cooling is unfavourable to both reactions.

CASE II

H. M. is an artist, aged 64 years, he was admitted for cardiac failure with venous congestion and slight oedema, but without sign of valvular lesion. There is no history of paroxysmal haemoglobinuria nor evidence of syphilis. Whilst in hospital his skin was found to be abnormally sensitive to cold, and he then gave a history, extending over a period of twenty-five years, of nettles rash occurring on any surface exposed to cold.

In this patient cold produces urticaria locally in the skin, exposure at 0° and 10° C for ten minutes gives a typical urticarial reaction, but his responses to varying degrees of cold and length of exposure are somewhat variable from day to day. Prolonged exposure of the arms to cold water gives no haemoglobinuria, *in vitro* tests provide no evidence of a haemolysin in his blood. His serum, however, contains a dermolysin, which can be transferred readily to the skins of normal subjects by injection, causing them to react similarly to cold.

CASE III

W. W. M., a boy of 9 years, had frequent attacks of red urine for three winters, but is said to have had none for the last four years. The attacks always followed exposure to cold. The boy's Wassermann reaction was positive four years ago, but is now negative (he has been receiving antisyphilitic treatment). There is no history of skin eruptions.

This boy, giving as he does a typical history of paroxysmal haemoglobinuria, has not present a haemolysin in the blood, as shown by *in vitro* tests. The skin has been tested with varying degrees of cold from 0° to 15° C, but no whealing can be obtained. The skin of a control subject injected with the patient's serum fails to react to cold.

On the basis of observations upon these three patients, and upon other observations to be described at a later date, we conclude that there are three types of case in which there is a specific reaction to cold—namely, simple haemoglobinuria, simple urticaria, and haemoglobinuria and urticaria combined. The haemoglobinuria in the first and third types is due to a haemolysin, the urticaria of the second and third types to a dermolysin. We have as yet insufficient evidence to show that these two substances are either identical or different, but this question is being investigated further, we have evidence, in their frequent association and in the general resemblance of the corresponding reactions, that the two substances are closely allied pathogenetically.

RADIUM TREATMENT OF INTRINSIC CARCINOMA OF THE LARYNX*

BY

N. S. PINZI, M.B., M.R.C.S., L.R.C.P.,
MEDICAL OFFICER IN CHARGE OF X-RAY DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL,

AND

DOUGLAS HARMER, M.B., B.CHIR., F.R.C.S.,
SURGEON, THROAT DEPARTMENT, AND LECTURER ON DISEASES OF THE THROAT, ST. BARTHOLOMEW'S HOSPITAL.

At St. Bartholomew's Hospital researches in radium therapy have been carried out since 1913, and many different types of growth have been treated. At first we employed large doses of radium, either as external applications or buried in the centre of the growths. With these methods it was found that there was too much local destruction of tissues. Radium burns were often produced and the wounds healed slowly. Necrosis and sloughing of deeper tissues were caused, and in many instances secondary haemorrhages occurred. After fifteen years' experience we have come to the conclusion that radium should be buried in the tissues whenever possible, and that as a rule small amounts should be used for long periods. To obtain a uniform irradiation platinum-iridium needles containing radium are buried around the growth, the greatest care being taken to prevent sepsis.

With smaller doses and better technique our results have gradually improved, and four years ago we devised an operation closely resembling that of Professor Bayet for the treatment of intrinsic cancer of the larynx which we hoped might give better results than the more mutilating treatments such as laryngo-fissure and laryngectomy. We have now treated 15 cases of carcinoma of the larynx by this method, in 13 the diagnosis was confirmed by microscopic sections before they were treated.

Method Employed

A skin incision is made over the thyroid cartilage, starting at the centre of the hyoid bone and extending outwards and downwards along the posterior border of the thyroid cartilage. The infra-hyoid muscles are exposed and split longitudinally. The internal aspect of the thyroid cartilage is exposed, the perichondrium covering it is divided and stripped backwards and forwards. The greater part of the cartilage is then resected. Thus a large window is made in the thyroid cartilage, but a framework is left consisting of the four margins. By this means the outer surface of the growth covered by the perichondrium is exposed. It is important not to destroy this capsule or to cut into the growth. The cartilage is removed for two reasons—to allow the needles to be placed as close to the growth as possible, and to prevent the perichondritis or necrosis which may be caused by the radium.

From five to ten radium needles are thus inserted lying parallel to one another and vertical. To keep them in position the ends of the needles are tucked under the framework of the cartilage. Care is taken that the needles do not penetrate into the growth or into the larynx. At the lower end of the wound, if the growth is subglottic, the needles are pushed inside the cricoid ring, but in this situation the tissues are often so thin that occasionally the needles may perforate the air passage.

Each needle has attached to it a piece of linen thread soaked in a solution of flavine 1 in 1,000. This material seems to cause less irritation than silk or others that have been tried. The threads are all tied together and buried beneath the muscles. Double sutures are inserted into the skin, half of them being tied at once to close the wound completely, and the other half left so that they can be tied later after the radium has been removed. No drainage is employed, and the skin incision is completely sealed with a collodion dressing. If the growth has extended across the middle line, a second window is made in the thyroid cartilage on the opposite

* A paper read at the Second International Congress of Radiology held at Stockholm.

sids, and needles are buried there also. A low tracheotomy is then performed. This is deliberately made the last stage of the operation to prevent infection of the laryngeal wound. Tracheotomy has been performed in all the cases because the reaction which results from the radium may cause so much swelling that the glottis may become temporarily obstructed. In six of the cases the patient could not have breathed satisfactorily without a tracheotomy tube.

The needles have been left *in situ* for periods of from four and a half to eight days, according to the dose of radium employed and to the extent of the growth that had to be treated. At the end of the treatment the wound was found to be infected in every case. In some of them there was definite pus, while in others the exudation was serous, blood stained, or fibrinous. Slight rises of temperature (99° to 101°) were common, but in only one case was the wound septic enough to cause anxiety. Cough has been a prominent feature of all the cases while the radium was *in situ*, and a good deal of sticky mucus has been secreted in the larynx. In no case has the inflammation extended downwards and caused bronchitis. With one exception, no shock has resulted from the treatment. There has been practically no pain or discomfort, and none of the patients has been seriously ill.

The time of the removal of the needles depends to some extent on the amount of reaction and inflammation in the wound. In one case the suppuration was so severe that the needles had to be removed earlier than was intended. In such an instance the skin wound requires drainage for several weeks. After removal of the needles the wound should be thoroughly irrigated with hydrogen peroxide or flavine and unless pus has been present it should be closed completely wherever possible. If there is much effusion a small drainage tube may be retained for a few days. Some swelling and induration of the neck results from this treatment, and may persist for a month or two. Ultimately the wounds heal soundly with soft movable scars.

Changes in the growth itself occur rapidly, and even in ten days the lesion may appear less nodular. Often the surface is then coated with a layer of white fibrin. The surrounding parts are generally oedematous, and in some instances the swelling may occlude the glottis. Later the inflammation subsides, and after six weeks all signs of growth may have disappeared, leaving the cords symmetrical and equally movable. About this period the tracheotomy tube can usually be removed.

Dosage and filtration.—We have throughout used a 0.5 amp filter of platinum containing a small percentage of iridium. The applicators have been in the form of needles 2 cm and 1 cm long, containing respectively 1 or 0.5 mg of radium element. In some cases these needles have contained 0.9 and 0.45 mg. On the average eight needles, seven long and one short, are used if one side only is being treated, and about twelve for both sides. With about 7 mg of radium element in the wound we usually leave the needles *in situ* for six or seven days (see table). In some cases about 30 per cent of a full dose of heavily filtered x rays has been given during two or three days immediately preceding the operation.

Theory

It is known that if a transplantable animal tumour be given a certain dose of radiation *in vitro* such a tumour can no longer be transplanted. This is called the lethal dose, but a lethal dose cannot be administered to the whole of a tumour in the human larynx or in an animal because the effect on the surrounding tissues is too severe. By embedding radium in a growth, however, parts of it will receive such lethal dose. Now if an animal tumour which has received *in vitro* a lethal dose and not very greatly in excess of this be implanted, it is absorbed and immunity to subsequent implantations of the same tumour is conferred on the animal.

One of us has advanced the theory that the administration of the lethal dose to parts of the tumour *in vivo* renders the remainder of the growth more susceptible to moderate doses of radiation. Therefore radium needles or seeds may produce better effects than homogeneous irradiation of the tumour. When such a big dose is given

the tissues are very susceptible to bacterial invasion, so that the most meticulous care must be taken to avoid sepsis. This we have borne in mind throughout. Apart from this action the effect of the rays is selective, the cells of the growth being more vulnerable than the normal cells. The wonderful restoration of the vocal cords, so that it is not even possible to say which side has been diseased, is evidence of this.

Results

Of the 15 cases treated, 14 were males and one a female, with ages varying from 45 to 67. Patients were selected who were not too old and who had a reasonable expectation of life. They can be grouped in three classes as follows.

1 Early cases in which the growth was strictly confined to one vocal cord and did not involve either the anterior commissure or the arytenoid cartilage—namely, cases that could have been treated by laryngo-fissure. In this class there were 8 cases. In 6 the growths entirely disappeared, and the patients have remained well for periods of from one to three years. In all of them the affected vocal cords have become freely movable. In some of them the vocal cords have recovered to such an extent that it is now almost impossible to detect on which side the growths were situated. Such results are far superior to those that can be obtained by cutting operations such as laryngo-fissure. The voice results are also excellent, the worst voices being better than the average obtained by laryngo-fissure. To demonstrate this feature a gramophone record of an exceptionally good voice following thyrotomy was prepared, and was no better than the good results obtained after radium treatment. In one case the growth diminished in size, but a stenosis of the glottis resulted, and the patient died suddenly eight months later of unknown cause. In the other case no real improvement resulted from the treatment.

2 Advanced cases in which the disease was intrinsic but had crossed the middle line in front and involved the other vocal cord. These cases could only have been cured by some form of laryngectomy. There were five cases in this class. One patient has remained cured for four years, his vocal cords are freely movable and have a normal appearance, but the voice result is not as good as might be expected (record given). In one case, a male, the disease in the larynx entirely disappeared and the voice became normal again but recurrence took place a year later in the tracheotomy wound, and he died eight months afterwards. In one case the growth shrank, but a stenosis of the larynx supervened and later it recurred, and the patient died twenty-one months after operation. In one no improvement was noticed. One patient died of chloroform poisoning before the operation was completed. The voices in the two cases in this group in which the disease disappeared were infinitely superior to anything which can be obtained by means of an artificial larynx, and in one of them the voice became normal.

Many patients will even prefer an increased risk to life rather than lose their voice permanently. As far as our evidence goes radium treatment does not increase this risk.

3 Inoperable cases in which the disease had extended into the pharynx or through the laryngeal cartilages into the neck, with enlargement of the cervical glands. In this group there were two cases. In one case the growth entirely disappeared and the glands which contained carcinoma, were removed by operation. The larynx remained healthy for two and a half years but afterwards the vocal cord became thickened again owing to recurrence. In the other case the growth shrank greatly, but the patient died after fifteen months, probably as the result of metastases in the mediastinum.

This last class of case can also be treated by heavily filtered x rays. In one patient who has recently been treated by this means an extensive ulceration involving the greater part of the cavity of the larynx has entirely healed and the growth has already greatly diminished.

These results are encouraging, but obviously it is too early at present to be certain to what extent the cures are permanent. It is quite possible that radium will be found to be the best method of treatment in all cases of intrinsic

Case	Sex	Age	Symptoms (years)	Date of Operation	Number of Needles	Needles Retained (days)	Tracheotomy Tube Retained (weeks)	Cured (years)	Arrested (years)	Dead (years)	Larynx	Cords	Voice

carcinoma of the larynx. There seems to be no doubt that in the early cases in which the disease is strictly localized to the vocal cord a high percentage of cures can be expected, and the after-results are far superior to those which have been obtained by operation. In a favourable case the vocal cord may become absolutely normal again and freely movable. The voice may be completely restored (6 cases), and the larynx does not appear to be weakened in any way.

In advanced cases there seems no doubt that radium should always be tried before laryngectomy. If the disease is not completely eradicated within three months, or if any induration remains, the radium treatment should either be repeated or an operation such as laryngectomy performed. Even in inoperable cases it seems probable that with careful selection some relief of symptoms and some prolongation of life may be obtained by this method.

Lantern slide diagrams of the condition of the vocal cords before and after the treatment were shown. Gramophone records which had been specially prepared free of cost by the kindness of the Columbia Graphophone Company were used to illustrate the voice results, and for comparison the records of two cases treated by the operation of laryngo-fissure were included.

Case Histories (July, 1928)

Case 1—Extensive growth involving the right side of the larynx the anterior commissure and the front of the arytenoid cartilage the greater part of the glottis was occluded. The patient was seen in consultation with Sir St. Clair Thomson and told that the disease could only be treated by complete laryngectomy or by radium needles. He was warned that radium treatment was still in its infancy and that we had no previous experience whether it would succeed in his case. After careful consideration he refused to have a laryngectomy performed and decided to try the radium treatment. Six months later he was again seen by Sir St. Clair Thomson who remarked that 'If we can see him this time next year without a recurrence it will be a splendid case. Now, nearly four years later he has a perfectly normal larynx with freely movable cords, and a good voice.

Case 2—The growth had been removed three years previously by laryngo-fissure. There was an extensive recurrence involving the right half of the larynx. Again the choice lay between complete laryngectomy and radium and he was strongly advised to have the former. As he absolutely refused to undergo laryngectomy radium needles were inserted. The growth was found to have extended through the thyroid cartilage into the tissues of the neck. Twenty-eight needles were inserted on the two sides and the growth almost entirely disappeared, leaving a moderate stenosis in the subglottic region. His health gradually failed and he died fourteen months after the operation from chest troubles, which were probably due to secondary glands in the mediastinum. Although his larynx never became normal, there was at no time any active recurrence of the growth in it or in the neck.

Case 3—A medical man with an extensive growth on the right side of his larynx involving the anterior commissure. To cure the condition a complete laryngectomy would have been necessary but the operation was refused and fourteen radium needles were

buried in the two sides of the larynx. All signs of the disease in the larynx disappeared rapidly. In two months the larynx had a healthy appearance both cords moved freely and the voice was absolutely normal. Twelve months later he suddenly became hoarse again and a hard swelling was discovered in the position of the tracheotomy wound. It was explored and found to be a malignant growth surrounding the trachea, and inoperable. His health rapidly failed in spite of external radium treatment and he died twenty months after his operation from a recurrence in the neck, the larynx having remained healthy throughout.

Case 4—Apparently an early case with a localized hard fibrous growth confined to the right vocal cord. The disease did not respond well to radium treatment. Subglottic stenosis of the larynx resulted necessitating a permanent tracheotomy tube. The patient died unexpectedly eight months later of heart failure and a post mortem examination showed that there was a mass of scar tissue below the vocal cords containing small islands of carcinoma cells. It is probable that in this case the needles were not inserted low enough to treat the disease in the subglottic space properly.

Case 5—An extensive disease of long duration involving both sides of the larynx. The growth responded badly to radium treatment and a subglottic stenosis resulted. The patient's general health and voice were poor, and he died two years later.

Cases 6 and 7—In each instance the growth was an early one and strictly confined to one vocal cord. Good results were obtained. The larynges became healthy again with freely movable cords and normal voices.

Case 8—A very extensive carcinoma involving the whole of one side of the larynx. Suspicious glands could be felt in the same side of the neck. Previously he had been treated for twelve months by continued small doses of x rays. Eight radium needles were buried and all traces of the growth entirely disappeared, leaving a healthy larynx. The glands were removed later and found to be infected with carcinoma. His larynx voice and general health have remained normal for nearly three years.

Case 9—A localized growth involving the left vocal cord and anterior commissure. The cord moved sluggishly, the voice was husky and weak. Operation by Mr. Rose. After treatment the growth rapidly disappeared and the larynx assumed a healthy appearance. The cord now moves freely and the voice is normal.

Case 10—This patient had suffered from syphilitic laryngitis for many years, and it was doubtful when the carcinoma started. The disease was very extensive and could only have been treated by complete laryngectomy. Radium needles were buried but the growth did not improve with the treatment and an external fistula developed which ultimately became infected with the disease. Death occurred fourteen months after the operation.

Case 11—A localized growth of one vocal cord which disappeared immediately after radium treatment. The vocal cord now has a healthy appearance and moves freely. The voice is normal.

Case 12—An extensive growth involving the whole length of the right vocal cord with marked swelling of the ventricular band. Two-thirds of the glottis was occluded by the growth. After treatment the swelling subsided slowly. The vocal cord is now slightly thicker than normal but moves freely, and the voice is strong.

Case 13—An extensive growth involving the whole length of the left vocal cord the anterior commissure the hyoid and the epiglottis slightly, and the subglottic region. Seen by Sir St. Clair

Thomson, who agreed that the growth was too advanced for laryngo-fissure, and that the patient was not strong enough for laryngotomy because he had an enlarged liver and had suffered from haematemesis. Radium needles buried under a local anæsthetic. The growth rapidly shrank and had entirely disappeared in three months. The cord became freely movable although the edge was slightly swollen by oedematous fringes. He now has a loud hoarse voice.

Case 15—A fairly extensive growth involving the whole of the right vocal cord with infiltration of the ventricular band. So far the growth has not responded to radium treatment and a further operation will probably be necessary.

EXAMINATION OF THE EYES AND EYESIGHT OF YOUNG CHILDREN

BY

THEODORE WHITTINGTON, M.D., D.O.M.S. LOND.,
Chief Ophthalmic Assistant King's College Hospital, Ophthalmic Surgeon Queen Mary's Hospital for Children and South Eastern Hospital for Children

THE subject of this paper forms, I imagine, part of the work of all of us here, whether we be ophthalmologists, school medical officers, or general practitioners interested in eye work. Much has been written about the examination of children in elementary schools. Statistics dealing with very large numbers have been published by Mr. Bishop Harman¹ and Dr. James Kerr,² to whose useful work we are much indebted. It is the examination of young children, including those below school age, about which I wish to speak, and I should like to insist that my remarks apply to the children of all classes, and not merely those attending school clinics. For this subject forms an important part of what we have been discussing—"visual efficiency" affects "working ability" no less in childhood than in after years, in some ways, indeed, more so. Vision being our most important special sense, it is possible for a child's whole "outlook" in the widest sense of the term, to be affected by his sight.

There are several factors peculiar to childhood which make a routine examination advisable. These factors ought to be more appreciated by the medical and teaching professions, for, roughly speaking, it is only those young children attending council schools who get a routine examination of their eyes. Young children seldom complain of their sight. They know no better. Eyestrain and the mental fatigue produced thereby are supposed to be part of the irksomeness of doing lessons. As I have already suggested, a child's character, health, and habits are liable to be affected by its sight. The "beautiful little needlewoman" or the "wonderfully studious boy" may be the result of short sight. The child who does not see across the room clearly, and who can scarcely see at all down the street, has few distinctions from his books and toys. Such children who are taught in small dames' schools, home schools, preparatory schools, or by governesses do not get noted as do the children in the large classrooms of the council schools where a blackboard is in daily use. There is much need for propaganda on this matter. So, too, a rebellious hatred of lessons or so-called stupidity may be the result of a serious defect of vision. In order to read, a young child has to see every single letter, and thus at a time when the eye is not fully developed, is still growing, and is ordinarily long-sighted. Children with their great power of accommodation may, for a time at any rate, disguise a big defect, and such children will pass an examination which merely depends on the reading of test types.

As well as the growth of the eyes, we have to remember the development of their functions. Binocular vision, or bifovent vision, should become well established within the first few years of life, but this faculty, in association with the proper muscle balance of the eyes has to be

acquired. Like walking, it is easily upset or retarded in infancy.

Variations from the normal, therefore, as regards fixation, muscle balance, and binocular vision, are the most important clues we have which lead us to discover defects of vision in early childhood. From this it follows that we shall have to distinguish between the spurious squint of the young infant and the incipient squint of the older child. From our clinical experience we know the importance of early treatment, after the seventh or eighth year we know that treatment of such defects often fails in the desired result, which is to obtain complete binocular vision. We bear all these facts in mind and also do not forget our general medical knowledge of children. In this way the examination by an ophthalmic surgeon may not infrequently be the starting point of great improvement in the child's health, mental and physical.

Certain simple details of a routine examination³ carried out on these lines may possibly be of help to some. The examination should be made in a large room which can be easily and quickly darkened. Good daylight is only needed at the place where the surgeon and child sit. Test types are artificially illuminated by standard illumination, using daylight lamps. When a number of children are to be seen, the brighter and older ones are first examined, whilst the others observe the proceedings without, however, being able to see the test objects. The child is seated to the left of the examiner, and behind the child is a lamp for retinoscopy. The child is allowed time to get accustomed to the surgeon's presence whilst the latter enters details. The surgeon then rapidly looks for external signs of inflammation, etc. The lids are carefully examined. Definite blepharitis is, of course, well known to be a suspicious sign of eyestrain, and the clearer the child the more suspicious is this sign. The presence of quite inconspicuous scales at the roots of the eyelashes, apart from any redness, is I think, quite as important, and more often than not indicates an error of refraction requiring treatment. The condition is a slight seborrhoea due to over-secretion, the result of reflex irritation produced by eyestrain. The presence of follicles inside the lower lid makes the examiner suspect the general health or hygiene.

Next, the movements of the eyes are tried. With small children the retinoscope mirror rarely fails to attract, and for a screen to cover one or the other eye the examiner uses the thumb of his left hand placed on the child's head. I need not further detail this examination to an audience of ophthalmic surgeons, except to remind you that, during the various movements of the eyes, opacities of the cornea or in the pupil area should be noted. If the lids, fixation, convergence, and other movements and muscle balance, as tried by the above methods, all appear normal and the cornea and pupil areas are clear, the child, being an infant, has passed his test.

In slightly older children, the toddlers of 3 and 4 years the vision is further tested by pictures of familiar objects. Little children will whisper the names to a friendly examiner as the pictures are pointed out by a nurse. If the child is reading—if one may so describe it—the pictures well, each eye singly may be tried. Other children who can scarcely be persuaded to read the pictures have the eyes alternately covered. If the child dislikes having one eye covered and does not mind the other eye being covered this latter eye should be suspected of being defective. Other things being normal, I do not think that at this age any further test of each eye separately is necessary. Such pictures are not drawn to exact scale like those of Snellen's type and the "E" test, but a small child who "reads" the smaller objects freely and easily has sufficiently good vision for his age. No preliminary training is required and there is very little mental fatigue. A picture book may be first shown to the child to encourage him to talk, and then he should be told to look in the distance. I have several times spotted myopia and other bad defects at an early age when an otherwise bright child has appeared to take no interest in the distant pictures. Although high myopia is relatively rare in infancy, anyone who does much children's eye work not infrequently meets with it. I have notes of many cases of high myopia in early childhood,

* A paper read in the Section of Ophthalmology at the Annual Meeting of the British Medical Association, Cardiff 1928.

¹ See summary of the discussion on visual efficiency and working ability. *British Medical Journal* August 4th p. 205.

the worst case being one of 14 dioptries in a child a year and nine months old.

If a child does not read these pictures, retinoscopy is done straight away and the position of the corneal reflex is noted. The room is darkened and the child looks into the distance over the examiner's shoulder at a nurse whose duty it is to attract its attention. Children with obvious refractive errors are at once spotted, and, together with doubtful ones, are referred for retinoscopy under a mydriatic. With the arrangement above mentioned this is all done very quickly, and there is no moving of the child into a dark room.

A young child may have 3 or 4 D of hypermetropia at 4 years of age and have no need of treatment if it has passed these tests. In this connexion I should like you to consider some figures published by Mr. Bishop Harman,¹ together with the results of an examination by Dr. Margaret Hogarth.² Mr. Bishop Harman tested 350 children between the ages of 4 and 7 years under a mydriatic, and in round numbers found 65 per cent with hypermetropia not exceeding 2 D or with astigmatism not exceeding 1/2 D, which he calls a good average eye, and 35 per cent defective through all causes, including six myopes. With this standard you notice that he found 35 per cent defective. On the other hand, Dr. Margaret Hogarth, by testing very carefully the vision of 800 Peckham children between the ages of 4 and 7 years by the "E" test, found that 86 per cent had normal visual acuity. I think we must allow, therefore, for the fact that, although the young child is normally somewhat hypermetropic, yet at the same time he is endowed with compensatory powers of accommodation. If, however, binocular vision appears to be defective, a child with as little as 2 D of hypermetropia may need to have this corrected.

Children who can read go through all the above tests, but are examined by Snellen's test types. For the sake of the youngest children it is wise to use only the letters of the first half of the alphabet, and for the top letter to be a "B" or a "D," for example. A "Z" or an "X" at the top they may not be so sure of, and this may cause them to err.

In all cases note how they read as much as what they read. For example, a boy aged 8 read 6/6 with each eye singly, but after 6/18 the reading got slower and more deliberate, and the boy shut his eyes at intervals. It had been previously noted that he had a few scales at the roots of the eyelashes. He had 2.5 D of manifest hypermetropia, and stated that his eyes were sometimes sore. Another boy saw 6/6 with each eye, but read the last few lines slowly and deliberately. He stated that his eyes troubled him when reading, and retinoscopy showed 5 D of hypermetropia. Both these children would have been passed if the mere reading of the type had been the only standard. Besides slowness and deliberateness and a strained attitude, the examiner should note whether the child stops reading, shuts the eyes, and starts off again, also whether the child screws the lids up, and, if so, should tell him to open wide and try if he can still see well.

Provided always that no abnormalities are noted under any of the above headings, and no complaints are made about the eyes, the following rough standards of vision are used.

A child of about 10 years of age and over should read 6/9 with each eye and a child between 7 and 10 years should read 6/12 with each eye. Such children are passed.

I have notes of 4,186 children whom I have examined, as a routine, on these lines at Queen Mary's Hospital for Children at Corsholton.³ This is a hospital of 800 beds for orthopaedic, tuberculous, cardiac, and convalescent cases coming from the County of London. Slightly over 20 per cent were found defective from all causes. Their ages varied from 2 to 16, the average being 11. Of 500 children, however, whose average age was slightly below 8, less than 15 per cent were found defective. Statistics which do not give the average age and visual standards lose something of their significance. There are two chief reasons why less than 15 per cent of these 500 younger children were found defective: (1) because of the lower standard demanded, and (2) because of the comparative rareness of myopia.

Thus, among the 4,000 or more children of the total average age of 11 who were examined, the average age of the hypermetropes was 10 years and that of the myopes 12½ years.

Next we come to the consideration of retinoscopy when examining young children. Do we need so completely to paralyse the ciliary body as to abolish the normal tone of this muscle not rest? Is it not enough that accommodation should be absent during retinoscopy? We do occasionally meet with spasm of accommodation in older children, hyper-sensitive and worried about school examinations, but I have not met with it in small children. Tablets containing cocaine and atropine 1/200 grain (previously shown to the child as "little sweets") are placed inside the outer part of each lower lid at the same moment whilst the seated child looks up at the surgeon or nurse putting them in. The tablets rapidly soften on the everted lids, and, when these are released, dissolve in the lower fornix without touching the sensitive cornea. If the child is examined an hour and a half later in a darkened room—not, be it noted, in a dark cupboard-like place—where he will not be frightened and where his attention can be attracted to look in the distance, this method is found quite efficient. It is certainly kinder to the child than drops of ointment used for three or four days, often very inefficiently inserted and often associated with struggles and crying at each attempt, of which I myself have vivid recollections in my early childhood.

If ointment is prescribed the best method is the use of ointment put up in soft gelatin capsules such as are made by Messrs. Duncan, Flockhart and Co. The ointment can then be safely and efficiently squeezed inside the lids by the most inexperienced, it is of a low melting point, and comes out of the tube sterile.

In infants and young children the angle of astigmatism must be accurately found when doing the retinoscopy. If a retinoscope with two mirrors is used one can always follow the bar of light moving with the mirror, and the angle in one meridian is checked by the angle found for the opposite meridian. The child should be looking straight at the mirror when the angle is being accurately determined. In older children final subjective testing may be attempted, especially if retinoscopy has indicated the need for strong cylinders. A trial frame is used in which the cylinder can be easily turned by the child himself. Put the cylinder in a known wrong position, and let the child have the amusement and pleasure of getting clearer vision by turning the little wheel. Comparatively young children will often thus make fine adjustments of a strong cylinder when the game has been explained to them.

So much for routine testing. It cannot be too strongly insisted that the mere reading of lines of type never should be the sum total of "sight-testing," and that young children of all classes should undergo a routine examination somewhat on the lines here suggested.

A final word about the children who are brought to see us because of some supposed defect or because of some complaint about the eyes. We have already noted that quite young children do not complain. Squint or suspected squint is by far the commonest cause of mothers bringing a young child. Of 550 children seen privately for all causes, 83 (15 per cent of the total) came to see me for this reason, and the average age of these children (when first seen by an oculist) was 4 years. Older children do complain of their eyes. For those who have some definite abnormality treatment is usually obvious. I would like to refer to those in whom no such defect is found. Forty-nine of these 550 (that is, over 8 per cent), of the average age of 10 years, were found with normal vision and, as regards their refraction, came within the limits of the "good average eye" of Mr. Bishop Harman.¹ Yet they were brought because of symptoms referred to their eyes, principally frontal hoodedness, inability to read for long, frowning, twitching of the eyes, etc., or severe mental fatigue after lessons, or because of a general tendency on the child's part to use the eyes, as it were, as a peg on which to hang his troubles. Not counting two cases of chorea and one of definite acidosis, the remainder come under the heading of what I call "anxiety strain." All young children are apt to be uncontrolled in their actions.

and the nervous, excitable, worrying type is especially apt to throw an excessive amount of nervous energy into whatever it does, accommodation included. Being anxious and over-intent about their lessons, they accommodate for the book nearer than it is, draw closer, therefore, and have to accommodate still further, overdo that, and get closer still. With their big power of accommodation they keep this up for a while. The so-called accessory muscles of accommodation (orbicularis, corrugator, frontalis) are reflexly put into strong action, and this helps to aggravate the ache in those regions. Later the effort becomes too great to be sustained. Convergence gives out, I think, first (letters are said to run into each other), and accommodation fails, the whole process is followed by headache and severe mental fatigue following on the expenditure of nervous energy. These children are of the type who have 'night terrors'. The treatment of these cases is the treatment of the child rather than its eyes. The cause of the trouble has to be explained to mother and teacher, and in a certain degree to the child, in order that its habits may be altered. The family doctor's help is obtained and a daily dose of bromide may be of more use than a pair of spectacles. Our reputation will suffer if we limit our examination to the correction of half a diopetre of hypermetropia in an individual with 14 dioptries of accommodation. It will be enhanced by the explanation that glasses are not necessary, and by the subsequent improvement in the child's health.

THE KIDNEYS IN PNEUMOCOCCAL INFECTIONS

BY

A. VICTOR NEALE, M.D., M.R.C.P. LOND.,
RESIDENT MEDICAL OFFICER, CHILDREN'S HOSPITAL, BIRMINGHAM

CONFLICTING records appear in the literature concerning the relationship to nephritis of invasions of the body by the pneumococcus of Fraenkel.

Sir Thomas Horder¹ in a recent address remarked that it had been suggested that pneumococcal infections were responsible for a large proportion of hæmorrhagic nephritis cases, but he himself was unable to confirm the statement from his own experience.

Abrahams² discussing the results of 558 cases of typical lobar pneumonia occurring in the Aldershot Command during the war shows that although there were 61 deaths and 116 developed complications, only 2 cases developed nephritis giving the extremely low figure of 0.35 per cent.

Parsa³ discussing the etiology of nephritis in childhood believes acute catarrhal desquamative or tubular nephritis to be a condition occurring in varying degree as a result of acute infections such as septicaemia or pneumonia and being principally due to the circulating bacterial toxins the renal lesion being largely recovered from when the cause is removed, but severe cases may pass on to a subacute form to constitute nephrosis (Vollhard and Fahr). Several workers have attempted to associate the pneumococcus with lipid nephrosis. Vollhard⁴ observed the frequency of termination of the nephrosis cases by a pneumococcal peritonitis and Stolz⁵ in one case found bacteria resembling Fraenkel's organism in the walls of the glomerular capillaries, the tubule cells and the intertubular capillaries and in another case in the intertubular connective tissue. He is of opinion that the coccus in the kidney causes an inflammation that is at first acute but soon takes on a chronic form and results in injury to the tubules. It is suggested however that the germ may be a secondary invader. Variability in the incidence and degree of kidney lesions may be related to the particular virulence of the pneumococcal infection or even to a special group type of the pneumococcus.

It would seem, therefore, that some authorities attach significance to pneumococcal infections as a source of acute nephritis or as a starting point in the genesis of certain degenerative lipid processes in the renal tissue (nephrosis). Others have less regard for this suggestion. However, I have made some investigations into records and certain cases which will be considered.

An analysis of the urinary findings in 287 cases of acute lobar pneumonia in adults has yielded the following:

No. of Cases		Urine
Group A	10=3.4%	{ Albumin +++ Red blood cells + Granular and tub. casts +
Group B	32=11%	{ Albumin + No blood cells No casts
Group C	107=37%	
Group D	138=47.5%	{ Albumin - No blood cells No casts

In all the cases in Group A the urinary abnormality commenced between the third and tenth day after onset of the lobar pneumonia. In none of the above cases was there any history or clinical signs of previous renal disease.

Three other cases have been studied in which a previous history of nephritis was given, and which briefly were as follows:

Case 1—Nephritis onset two years ago. Apparently mild. Acute lobar pneumonia then occurred and ran the usual course. A few days after the onset of the pneumonia the urine showed features of an acute exacerbation of the nephritis: albuminuria +++ Casts and blood cells +. Marked improvement in the renal condition quickly occurred after the febrile crisis.

Case 2—Acute nephritis several weeks before but rapid improvement under treatment. Later onset of acute lobar pneumonia which ran a normal course ending by crisis.

Urinary Findings

	Albumin	Casts	Blood Cells
4 days after onset of pneumonia	++	+	+
6 (crisis)	+	+	+
8	+	-	-
15	+	-	-

Case 3—Known to have chronic nephritis. Urine before onset of pneumonia albumin + casts few blood cells nil. Latent had an attack of acute lobar pneumonia, with usual course and crisis.

Urinary Findings

	Albumin	Casts	Blood Cells
4 days after onset of pneumonia	+++	++	++
6 (crisis)	+++	++	+
10	++	+	-
20	+	+	-

The morbid anatomical conditions of the kidneys in 42 fatal cases of acute lobar pneumonia were investigated. In all the cases no previous renal disease had been suspected or detected.

- (a) Normal in 17 cases (40.5 per cent.)
- (b) Normal but signs of arterio-sclerosis in 3 cases (7.1 per cent.)
- (c) Cloudy swelling in 17 cases (40.5 per cent.)
- (d) Acute inflammatory changes in renal parenchyma in 3 cases (7.1 per cent.)
- (e) Chronic nephritis with superadded recent acute inflammatory changes in one case.
- (f) Small cortical hæmorrhages in one case.

It is the aim of the clinician to attempt to correlate a particular clinical feature with a particular anatomical lesion. But in the kidney extreme difficulties have presented themselves, and to-day many exceptions are found to certain views previously held. This is to be anticipated where such an anatomically complex tissue is concerned, and where probably the different elements although having in themselves particular functions cannot be considered as physiological entities, but only as units in cyclic action. Osler⁶ suggests that glomerular damage is the chief feature in 'pneumococcal' nephritis and Muir⁷ agrees.

An attempt to correlate the urinary contents with the probable renal damage may be made. The meaning of albuminuria occurring in a febrile state needs explanation.

It is unlikely that undamaged renal tissue would allow such an important plasma constituent to escape and be lost in the urine. Parsons' considers "fibrile albuminuria" indicative of the mildest form of renal inflammation—a form in which clinically there is no oedema, but which shows changes in the tubule cells on morbid anatomical examination.

A comparison between the urinary findings and the morbid anatomical findings may be seen in the following table.

	Urinary Findings	Necropsis
Nephritis	—	71%
Albumin + casts +, blood +	4.5%	—
Cloudy swelling	—	40.5%
Albumin +, casts - blood -	48.0%	—
Normal	—	47.6%
Albumin -, deposit -	47.5%	—

This table shows a comparison between renal and urinary findings in two series of cases. The number of cases showing normal findings at necropsy and normal urine findings is practically the same. Similarly, the acute nephritis figures closely approximate. The remaining large group, in which albumin, in variable degree, is the only abnormal feature in the urine, agrees closely with the number showing simple cloudy swelling ("parenchymatous degeneration" of MacCallum). The significance of this change in the cells is regarded as one of the earliest indications of a disintegrative effect. There seems no doubt, however, that such cells can resume a normal anatomical and physiological state. Authorities state that acute nephritis may occur at any stage of the disease in acute lobar pneumonia. In four cases occurring in the present series the condition was detected on the fourth, fifth, sixth, and eleventh days of the illness. In each case a simple albuminuria appeared before the presence of casts and blood cells. No relation to the length of the febrile period or other single clinical feature was found. In each instance the abnormal urinary findings only lasted for a maximum period of one week, and quick recovery appeared to be the rule. In the convalescent stage each patient conformed to the normal in response to renal function tests. Pneumococcal infection would appear to act adversely on kidneys which have suffered from a previous attack of nephritis but even in these instances the exacerbation is probably only a temporary matter, and return to a satisfactory condition may be anticipated in most cases.

Investigation of 112 cases of pneumococcal disease other than lobar pneumonia showed

Normal	46 = 45%
Albuminuria alone	45 = 44%
Albumin casts and blood cells	11 = 10%

Morbid anatomical findings in a similar series (65 cases) showed

Normal	25 = 38.5%
Cloudy swelling of parenchyma	45 = 47.0%
Pyæmic abscess	1
Nephritic changes	8 = 10%

Comparison of these results with those obtained in cases of pure lobar pneumonia shows that the readings are similar. No greater incidence of renal involvement is indicated, the degree and duration are apparently the same, and an early recovery of any renal lesion also occurs. It would also appear, therefore, that the particular focus or even extent of pneumococcal infection bears no relation to any consequent renal damage.

A remarkable constancy in the low incidence and the benign clinical features, *qua* renal symptoms and signs, was observed. In no case were any detectable cedema or uræmic symptoms found. Twenty-one cases of clinically pneumococcal infection in children under 7 years of age showed

Normal	5 = 23.7%
Simple albuminuria	12 = 57.2%
Albuminuria with casts and blood cells	4 = 19.0%

This small series suggests that a somewhat higher incidence of renal involvement occurs in the young patient. Clinically, however, as in the adult, a minority of signs occur and quick recovery is usual.

On clinical grounds the pneumococcus would appear to be a benign organism in relation to the etiology of nephritis. Immediate and ultimate prognosis of renal damage in infections due to Fraenkel's organism would appear to warrant optimism. That profound toxæmia occurs in many cases of pneumococcal disease is not doubted, but the views here suggested are in accordance with a low renal susceptibility thereto.

Conclusions

- 1 In acute lobar pneumonia nephritis is uncommon, but mild recoverable degenerative changes in the renal parenchyma are not uncommon.
- 2 Nephritis occurring in lobar pneumonia is of a mild type, of short duration, and apparently recovery is the rule.
- 3 Similar conditions occur in other pneumococcal infections.
- 4 The benign features of renal involvement in pneumococcal infection are similar in children and adults.

LATREME EMPHYSEMA INVOLVING THE GREATER PART OF THE BODY

REPORT OF TWO CASES

BY

JOHN A C MACEWEN, M.B., C.M., F.R.C.P.S.,
SURGEON, ROYAL INFIRMARY, GLASGOW

While surgical emphysema is fairly often met with in connexion with fracture of the ribs, it is, so far as my experience goes, generally fairly localized in a small area surrounding the site of injury. The only case seen by me which was comparable in extent and severity to those now reported occurred in Sir William Macewen's wards in the Western Infirmary, where, in addition to the chest, the head and neck were involved, and the emphysema extended down over the abdomen to the scrotum, which was greatly distended, resembling a large hydrocele.

The cases now reported occurred at about two months' interval, the second being admitted before the first was dismissed. Both men were critically ill on admission and for a considerable period thereafter, rendering thorough examination, even by x-rays, impossible.

The first a miner aged 44, was crushed by a fall of stone in the pit and complained of great pain on the right side of the chest on admission and inability to move the right arm probably due to fracture of the right clavicle, with injury to the brachial plexus. He had a curious audible crepitus on respiration which appeared to originate over the sternum. Emphysema had already appeared over the right chest and on applying strapping the emphysema spread rapidly over the right neck and face the eye being completely closed. Soon the whole face, neck, chest, and abdomen were involved the tissues becoming greatly distended, and the skin tense and glossy. The patient was quite unrecognizable. The scrotum was ballooned up. He had great difficulty and pain in breathing the pulse was good but the temperature was subnormal. In spite of incisions made to allow escape of the air the emphysema extended and next day the arms and the legs down to the ankles had become involved. Breathing was now laborious and the patient was cyanosed, the temperature was elevated and the pulse rapid and soft. After some days the emphysema began to subside very gradually so that, three weeks later it was very markedly less the face now being free although the thighs were still affected.

Although in this case fracture of the ribs was diagnosed clinically from the emphysema over them and the curious crepitant sound, no evidence thereof was found on x-ray examination, the fracture of the clavicle being the only definite x-ray finding.

The second case a man of 47 a forester fell from a tree, and was admitted in a collapsed condition with an obvious fracture of the right humerus about the insertion of the deltoid a dislocation of the same shoulder which was entirely masked by the emphysema which had already occurred extending from the fourth rib (which was fractured, together with the second and third ribs) to the angle of the jaw and over the shoulder. A crepitant sound was also heard in this case appearing to arise from the sternal region. About three hours after admission the

breathing was considerably embarrassed and the patient complained of great tightness in the chest and of severe headache. The emphysema had now greatly extended, involving both sides of the face (distending the eyelids, so that the patient could not see) both sides of the neck and thorax the skin being tense over these regions and, to a lesser degree the abdomen. The scrotum was moderately distended. There was a slight degree of emphysema in the left thigh.

During the night the patient was very ill. He was delirious, with a temperature between 102° and 103° F. the pulse was rapid and soft, respirations short and jerky and cyanosis marked. The emphysema now was at its maximum involving the whole body except the scalp, the skin being tense and glistening over a large area of the face, neck and chest. It extended to the feet, but was not marked below the knees. On squeezing the air out of the eyelids and forcing them open the conjunctiva was found to be affected. The accompanying photograph was taken after it had somewhat

subsided. At this time the crackling sound on respiration was audible at a distance. While the patient remained very ill for three weeks being generally delirious at night the emphysema gradually subsided but persisted over the chest and neck for about four weeks.

Both patients made a satisfactory recovery, leaving the hospital about a couple of months subsequent to admission. The first patient still suffers from the effects of injury to the brachial plexus, and the second had considerable trouble owing to the double condition of fracture and dislocation complicating his otherwise serious condition.

The notes on these cases are abstracted from the reports made by my house-surgeon Dr. E. Fischbacher and the photograph was taken by one of my senior students Mr. P. Brown.

AVULSION OF THE SCALP

BY

A. CREW BANKS, M.D., CH.B., F.R.C.S. ED.,
SURGEON, EAST SUFFOLK AND IPSWICH HOSPITAL.

Avulsion of the scalp is probably a much less common accident than formerly, owing to the better fencing of machinery and the modern fashion of wearing the hair short. In the three years 1924-26, however, the number of cases of partial or complete avulsion was 19.¹ It is more common in women than in men—for example 6 out of 9 cases at the Massachusetts General Hospital, quoted by Davis.² The avulsion is very often complete, the integument being torn at its thinnest part—the level of the brow and the line of separation passing between the loose areolar tissue underlying the epicranial aponeurosis and the pericranium. Death may take place from haemorrhage and shock.

Judging from the literature on the subject the end-results of treatment are none too good, while convalescence is tedious and not without danger from septic infection. The chief obstacles to successful treatment are the difficulty of obtaining an adequate blood supply for the new skin and the liability to sepsis.

Even the slightest pressure causes exfoliation of the skin, microbial infection below the crusts occurring in all the grafts.³ Abbé records a case in which 12,000 grafts were planted in four years.⁴

In a few cases when done shortly after the accident and in the absence of sepsis whole skin Wolfe grafts seem to have given sound end results—that is movable sensitive skin with no tendency to break down.⁵ In others a combination of these and Thiersch grafts have been successfully used.⁶

Porter and Shedden⁷ record a case where healing was obtained by removing several circles of bone from the calvarium to secure a dural blood supply.

Davison⁸ drilled fifty holes in a case where the pericranium had sloughed.

All these methods are illustrated in the following case, but final healing was only achieved by making use of a tubal graft after the Tngluacotian method. My only regret is that I did not think of it earlier.

The method of Porter and Shedden (which dates back to Indian scalpings) is perhaps not without risk of meningitis infection, and is contraindicated in young people owing to the active regeneration of bone. Replacement of the avulsed scalp is to be avoided owing to the danger of sepsis.

A girl aged 15 had her scalp avulsed in a machinery accident in September 1920 leaving only a narrow strip on each side and below the occipital protuberance. The bare area was extensively Thiersch-grafted but the higher grafts did not take well and the new skin showed a pronounced tendency to disintegrate. Large or smaller areas kept breaking down and ulcerating in spite of the most careful treatment and protection. Further Thiersch-grafting was done on several occasions during the next two and a half years but sound healing was never achieved.

The regions where disintegration most frequently occurred were carefully noted and in January, 1924 after due preparation of the head I removed eight circles of bone from half to three quarters of an inch in diameter and situated below these patches. The cavities were lightly packed with esul gauze granulations soon reached the surface and the epithelium grew over. Convalescence was untroubled and free from any complication whatsoever. For a time healing seemed to have been secured but after some months the same disintegrative processes recurred—no doubt owing to the dural blood supply being cut off by newly formed bone.

A year later several ulcers of various sizes were present in or near the old sites. Thiersch and Wolfe grafts were tried, but without permanent success, and consolidation seemed as far off as ever. The skin was mobile for about an inch at the sides and over the rest of the skull adherent to bone.

Stage 1—On February 10th 1926 a tubular skin graft 11 in by 4½ in with two pedicles was raised from the abdominal wall extending from just above the pubis well into the right flank and passing below the umbilicus.

FIG 1—Stage 2.

FIG 2—Stage 3.

FIG 3—Final stage.

Stage 2—Four weeks later the upper end of the graft was mobilized and attached along its free edge to the back of the right forearm below the radio-ulnar joint, the abdominal wound, which had been approximated by extensive undercutting, being nearly healed. As her general condition was not very good she was sent to a convalescent home for some weeks and did not find the position of the arm irksome during this time.

Stage 3—On May 20th the graft was detached from the abdomen and sutured to the edge of the scalp on the right side of the head. Contrary to expectations no great difficulty was experienced in keeping her comfortable nor in securing asepsis.

Stage 4—Seventeen days later the arm was freed and the opened graft sutured to the edge of the scalp on the left side. The bed was prepared by excising a corresponding area of the old skin a small oblong piece at each end—where it was mobile and the blood supply apparently adequate—being retained on a single

pchele in case of need for more skin (The distal half of these oblongs, each about 4 in long by 1½ in broad sloughed almost at once showing the poverty of the circulation even here)

Primary union was secured, but at one spot adjacent to the graft rather too much skin was removed and one of the small flaps was successfully used as a stamp graft to cover this

The patient has been fitted with a wig and has resumed work, and so far no tendency to break down has been anywhere observed. There is a definite degree of sensation in the skin flap. She can distinguish between heat and cold fairly accurately, can appreciate the separate points of a compass less than 1 in apart, and there is also evidence of epiritic sensation in parts. Painful stimuli are referred to the ends of the graft.

As an alternative a caterpillar graft from the back was considered. The girl, however, is small and slight, and excision of a sufficiently large area of skin might have interfered with function in addition to giving a poorer cosmetic result.

I am greatly indebted to my late house surgeons Mr. Tucker and Mr. Dyke and to Sister Rootham, who also is responsible for the photographs.

Memoranda:

MEDICAL, SURGICAL, OBSTETRICAL.

DEXTROCARDIA AND OTHER ABNORMALITIES

The following case merits publication from its unique character

A man was admitted to the Victoria Hospital with a history of abdominal pain and vomiting which had lasted about four days. On admission the temperature was 99° F and the pulse 90. The faeces were of the abdominal type. There was slight icteric tinge of the sclerotics and foul breath. Physical examination revealed tenderness and rigidity of the abdominal muscles on palpation of the appendix region also tenderness in the region of his umbilicus, with rigidity. This patient was well known to be the subject of dextrocardia.

A provisional diagnosis of acute appendicitis was made, and on the following day the appendix region was explored through a "gridiron" incision. The caecum could not be found in its right place, nor the appendix and it was concluded that this man was suffering from complete transposition of his viscera, and that the pain and tenderness in the right iliac fossa were due to colic. The wound was closed in the usual way. The patient stood the operation well and was comfortable after recovery from the anaesthetic.

He became worse next day and thereafter he sank rapidly, suffering from anorexia, vomiting, and rapidly increasing jaundice, and died two days later. Shortly before death the temperature rose to 105° and the pulse to 136. He remained in a comatose condition for twenty-four hours.

At the necropsy it was noticed that the fat in the abdominal wall was decreased and that there was some free blood stained fluid in the abdominal cavity. There was a large opening in the left dome of the diaphragm—larger than a man's fist—with smooth edges covered by peritoneum through this were herniated several coils of small intestine and transverse colon filling the thoracic cavity. The caecum and appendix were occupying the mid abdominal region. The appendix was not inflamed but elongated and kinked. There was a condition of acute haemorrhagic pancreatitis with adhesions all round the pancreas. The liver was congested and large and the portal fissure deep and pronounced the right lobe being well marked off from the left. The spleen was normal. The kidneys were longer but narrower than usual, and showed no pathological nor developmental peculiarities. The heart was transposed and the pericardium contained free fluid. There were springing from the arch of the aorta three vessels—a right common carotid, a right subclavian artery and a left innominate (the reverse of normal). The left lung was completely collapsed (it may never have developed) and on its parietal surface was a superficial area the size of a penny piece covered with a creamy exudate. The right lung looked like a normal left lung. The weight of the right lung was 15 oz 3 drachms that of the left 4 oz 2 drachms, while the heart weighed 10 oz 5 drachms.

I am forced to the conclusion that the immediate cause of death was acute pancreatitis, that the abnormalities recorded were developmental, and, in particular, that the hernial condition of the diaphragm must have persisted since infancy, having regard to the undeveloped condition of the left lung. As against this, it may be as well to

consider the possibility that in the absence of a developed lung and a weighty heart above the left dome of the diaphragm—that is, in the absence of counter pressure above the diaphragm—this portion of the diaphragm may have become weakened, and thus have paved the way to a hernial condition. If I am right in assuming that the hernial condition persisted from infancy, this is an amazing commentary on the adaptability of human life, when it is considered that this man was engaged in the arduous occupation of planting (and a planter's life is not a "dry" one), and at the least that the hernial condition—from which, in the absence of obstruction, he would not have died—must have lasted some time.

A CASE OF MULTIPLE DEFORMITY IN AN ADULT NATIVE

The case recorded below is of interest as showing that such gross malformation is compatible with power to walk well and to be able to grip well with both hands, so that the patient was able to lead an active life and to earn his living.

The patient was a member of the Wajji tribe of Kigoma Province of Tanganyika Territory, aged about 30 years and was seen at Kigoma in December 1927. The upper lip was split but the palate was intact. In the right hand the distal joint of the thumb was in a position of flexion. Only two metacarpals could be felt in the palm, that corresponding to the second being

CASE 1

CASE 2

double in part of its length. They each bore a carpal bone, but there was no division of the skin, so that there was only one large finger bearing a double nail. This finger had some flexion deformity. There was a very good grip with this hand. On the left hand there was no thumb and the second metacarpal was only half formed. The third was represented by a hair of bone joining the second to the end of the fourth. Otherwise the fourth and fifth metacarpals seemed normal and the only fingers present were the fourth and fifth which were partly webbed. There was a good grip with this hand also, but not so good as with the right. Each foot bore two appendages. On the right foot the outer appendage formed the greater part of the foot and seemed to contain a metatarsal bone ending in a small fleshy stump bearing a nail. The inner appendage of the right foot contained two tarsal bones was hooked, and bore no nail. The left foot was divided into two almost equal parts the outer being slightly the larger, and bearing a small fleshy toe having a nail. The individual bones of neither mass could be felt. The inner mass was crooked upwards and inwards and bore a nailless toe containing two tarsal bones. With a flat footed gait the patient could walk quite well.

Curiously enough, on the same day a native of the Wajji tribe of the Knsulu district of Kigoma Province was seen having an extra digit, bearing a nail but containing no bone, on the ulnar aspect of each hand. They were connected to the hand by a short stalk of flesh. Such extra appendages, either of the hands or feet, seem to be common in this tribe.

My thanks are due to the Director of Medical and Sanitary Services, Tanganyika Territory, for permission to publish these notes.

SPONTANEOUS PNEUMOTHORAX SUPERIMPOSED ON BILATERAL ARTIFICIAL PNEUMOTHORAX

The following case is interesting as showing with what a small quantity of lung tissue an individual may achieve a relatively efficient respiratory exchange

R F W a young adult male with bilateral pulmonary tuberculosis was admitted to Brompton Hospital on November 2nd, 1927. Artificial pneumothorax was induced on the right side on November 7th and on the left side on December 12th.

During the first few weeks the patient's temperature was erratic but it gradually settled and did not touch 99° F after January 10th, 1928. By February 7th he was getting up all day, and on February 13th he was allowed to go home. His home being within a few miles of the Brompton Hospital Sanatorium, Frimley, it was arranged that he should attend there weekly for refills and for some time he continued apyrexial well, and maintained his weight. Regular screening enabled the degree of collapse to be carefully controlled.

At the examination on May 22nd fluid was beginning to appear on the right side, on the left side only a shallow collapse was visible. During the next three months little change occurred. On August 21st after attending at the sanatorium for refills he returned home as usual driving a car for about six miles. On the way presumably the rupture of an adhesion led to a communication between lung tissue and the artificial pneumothorax. He felt a sharp pain in the left shoulder and began to suffer from shortness of breath. By 6.30 the next morning the discomfort was such that he had to send for his regular medical attendant who removed air from both pleural cavities thereby securing for him relief which however was only temporary. (It was impossible to measure quantities and pressures as no artificial pneumothorax apparatus was available.) Later in the day after the removal of more air he was moved to Frimley where a screen examination showed good collapse with fluid on the right and complete collapse on the left. In spite of this his temperature remained normal and his pulse and colour were good. At no time did he appear in the least cyanosed. During the next few days he more than once felt distinct embarrassment of respiration but he steadily improved the only treatment being rest in bed combined with the administration of small doses of potassium bromide and morphine hydrochloride in a mixture. By August 31st he was up six hours daily and was comfortable. He was discharged a few days later and has since remained perfectly well both sides being filled weekly as before.

I have to thank Dr H Batty Shaw for permission to publish these notes

S P WILSON,
Late House-Physician Brompton Hospital
and Brompton Hospital Sanatorium

B COLI MENINGITIS IN A NEWBORN INFANT

The case recorded below seems to be of sufficient interest to merit publication

A primipara aged 22 was under observation and treatment for toxæmia of pregnancy—manifested in headache and raised blood pressure—from mid term. At no time was any urinary abnormality detected.

On August 28th because of persistence of severe headache the induction was performed. She had then reached the thirty-seventh week of pregnancy. On August 30th at 7.40 a.m. labour commenced and the tube was removed. The membranes were then intact. On the same day at 11.55 p.m. a female infant was born it weighed 6½ lb and was 19½ inches in length. The infant appeared to be perfectly well and remained so until the afternoon of September 2nd when she had a screaming attack. This was repeated an hour later and it was noted that the abdomen was markedly distended. True convulsive attacks associated with a cephalic cry then set in and were frequently repeated. The abdominal distension remained until the following morning and was associated with the frequent passage of stools but not with vomiting. The convulsions became more frequent the abdominal signs diminished she became dyspnoeic the temperature rose to 100.2° and the child died at 9 p.m. on September 3rd—thirty hours after the onset of symptoms.

Examination revealed no other signs—no increase in tension of the fontanelle, no neck rigidity or limb rigidity, deep reflexes were not obtained the lungs were apparently clear there was no umbilical sepsis.

At post mortem examination made on the following day a purulent exudate was found over the convexity of the cerebrum and chiefly in the line of the vessels which were congested. The organs of the chest and abdomen were congested, but nothing further was noted except an offensive odour unusual at necropsies on the newborn. From the exudate a pure growth of *B coli* was obtained. From a cervical swab taken from the mother two days later a similar growth was obtained. Her puerperium was afebrile.

During birth, presumably, the infant swallowed some secretion infected with *B coli*. An extension from the intestine to the general blood stream followed, and meningitis was the gross manifestation of a *B coli* septicæmia. I can find no record of a similar case.

FRANCIS BRAID, M R C P
Honorary Assistant Physician Birmingham
Maternity Hospital.

Reports of Societies.

MEDICO-LEGAL ASPECTS OF FRACTURES

At a meeting of the Medical Society of London on November 12th, with Dr J W Carr, president of the society, in the chair, a discussion was held on the medico-legal aspects of fractures.

Professor E W HEN GROVER (Bristol), in opening, said that the habits that medical practitioners incurred in the treatment of patients varied inversely with the complexity of the condition. Fractures were just the type of case in which the actual injury appeared to be so simple that the public considered themselves to have sufficient knowledge to decide the adequacy and correctness of the treatment. Some time ago, with the aid of a legal friend, he had collected 50 consecutive cases in which some action was threatened or actually taken against a medical practitioner for alleged negligence in the treatment of fracture. The region of the body affected in these cases was as follows: clavicle 1, shoulder 9, elbow 3, radius and ulna 4, wrist 5, digits 3, femur (neck) 11, femur (shaft) 3, patella 1, tibia 5, ankle 5. The most striking fact which emerged from a study of this series was the prominent part played by x rays in 90 per cent of these cases; the neglect of a real x ray examination seemed to be the point on which the case turned. The classification of these legal cases, in all of which no x ray examination was made, according to the essential factor, was as follows:

	Percent
Diagnosis of fracture missed	56
Malunion not recognized	12
Complicating injury to bone or joint missed	18
Allegation by another practitioner could not be refuted	4

The missed fracture was most frequently that of the neck of the femur. Another group of missed diagnoses consisted of cases in which there was thought to be, not a fracture, but merely a crack, or perhaps it was considered that the fracture was impacted, and no special treatment was advised, and not until weeks or months later, when the weight of the body was placed on the limb, did full displacement occur. Next to missed diagnosis in frequency came the group in which the fracture was obvious, such as Colles' fracture of the wrist, or Pott's fracture of the ankle but some complicating injury was overlooked, in the former case perhaps displacement of one of the carpal bones or in the latter an injury to the astragalus. In the third group of cases the fracture was so obvious that it was thought quite unnecessary to have an x-ray examination, and the limb was put up and splinted, but malunion was allowed to remain and not recognized until long afterwards. Very frequently this malunion was of the nature of lateral displacement, and possibly if it had been recognized it might have been thought wiser to have been content with that amount of lateral displacement which very often resulted in no serious functional loss. In the x-ray picture, however, it was very obvious, and the argument was put forward by the patient and his friends that if it had been recognized it could and should have been corrected. The smallest group was that in which a more or less straight fracture was treated on conservative lines but owing to some circumstance or other the patient sought advice elsewhere, and the second medical man, in undertaking some operative procedure, deliberately or inadvertently made a statement to justify the operation which implied criticism of the first practitioner. In such a case the first practitioner would probably have been adequately defended if he had had a radiograph taken at the time of the injury. In the remaining 10 per cent of cases in which the question of x rays had not played any part the matter turned usually upon the hostile criticism of one medical man by another. Quite possibly the first criticism was inadvertently made, but eventually the critic was apt to become the chief accuser of his colleague in the court, and was usually persuaded to say in the witness-box a great deal more than he had intended. The speaker then dealt at some length with the case of Tyndall v. Alcock. He thought that if it had been argued for the defendant in

that case that he had carefully attended the patient and carried out the treatment had down in standard textbooks, but that he had made the flexion of the limb a little too full, the case would have been regarded as a mere error of judgement, and not as negligence. The prosecuting counsel, however, pushed the allegation that it was a perfectly simple fracture which had never been properly set. The speaker regarded that case as a grave miscarriage of justice and said that such a miscarriage had a wider bearing than the heavy misfortune suffered by one practitioner. In the early stages the great majority of fractures must be attended by men in general practice, and one could hardly blame a general practitioner if, influenced by the verdict and penalty in this case, he declined to have anything to do with a fracture, or merely adopted a non-committal policy of first aid, and awaited the result not only of x-ray examination, but of a second opinion, which might mean a delay of perhaps a week. Thus the golden opportunity of the first few hours, when reduction was comparatively easy, was lost. In conclusion, the speaker put forward three practical suggestions for reform, either in the law or in medical practice, so that the number of cases which came to court might be fewer and the cases of apparent injustice much rarer. He was well aware of the difficulties attaching to each of them. (1) A medical man before undertaking the care of a case of fracture should persuade the patient or his guardian to sign a paper indemnifying him against any action in case the result was unsatisfactory. (2) It should be made a definite ethical rule that when one medical man was asked to pronounce a verdict upon the work of another he should refuse to do so until he had had the opportunity of consultation with the man whose conduct was in question. (3) In High Court cases the judge should always have the benefit in technical medical matters of an assessor, a procedure already followed in county courts, where the judge had a medical referee sitting with him in compensation cases.

Dr JAMES NEAL (general secretary, Medical Defence Union) submitted that the position with regard to treatment of fractures was, from the legal point of view, essentially the same as it was with regard to all other forms of treatment. There was an implied contract between the practitioner and his patient that he would exercise reasonable skill and care in treatment, whether of fracture or any other injury or disease. Whether reasonable skill and care were exercised in a given case depended upon the facts which it was for the jury to decide on evidence, but it was not for the jury to fix the standard. All that the law demanded was the exercise of such skill and care as would be exercised by the ordinary practitioner in the same branch of the profession. Moreover, the term "reasonable skill and care" must be applied relatively, a rural practitioner could not be expected to have the same resources as a hospital surgeon. Failure to diagnose the presence of a fracture was the usual basis of a claim against a doctor. In all cases of doubtful diagnosis where there was any possibility of fracture an x-ray examination was essential, even when the presence of fracture was clearly established by ordinary signs and x-ray examination immediately after reduction had been effected should be resorted to for objective evidence that the limb had been placed in a suitable position. Modern advance in surgical treatment could not be ignored, and patients to-day expected far more perfect results than formerly. It might be necessary to repeat the procedures of manipulation, fixation, and x-ray examination several times until a perfect position was obtained, and any omission in these respects might conceivably render the practitioner liable for damages in the event of imperfect recovery. Each and every detail of the treatment might be challenged, even instructions given to the nurse or patient. The prudent man would therefore adopt precautions as a matter of routine. It was of the utmost importance always to avoid any appearance of carelessness. Only a few of the claims or complaints against doctors actually went to trial, and in the majority of these cases there had been some definite omission to take all reasonable precautions. It was a wise precaution to obtain a second opinion in any case presenting unusual difficulties. But if reasonable

skill and care were exercised from start to finish, doctors need not fear that litigation was any more likely to follow a case of fracture than other conditions. The real difficulty was that the question of negligence was one to be decided by a jury, and if the jury, even on the flimsiest evidence, found negligence it was almost useless to go to appeal. With regard to Professor Hey Groves's three suggestions, it was the opinion of the Medical Defence Union that a form of indemnity would not render the doctor immune from actions for negligence. He thought it impracticable for such an ethical rule as Professor Hey Groves suggested to be made, for anything which was calculated to lead the public to believe that the object of the profession was to safeguard the doctor would render the profession suspect, whatever it did. As for the assessor, this was a highly dangerous suggestion. If the judge was to be influenced by the advice of an expert, who might, for anything known to the contrary, hold the most peculiar views on the matters in dispute, the defence in every trial would be up against an unknown factor in addition to the jury who had already to be faced.

Mr ZACHARY COFF mentioned that there sometimes occurred a case, such as fracture of the hip, which had been neglected for some time, and with regard to which x-ray evidence furnished quite contradictory information. An x-ray picture might have been made, and then changes developed within a few weeks which made the line of fracture difficult to detect, and led to contrary opinions being expressed by equally competent surgeons. The x-ray picture might be very difficult to interpret, and grave charges might be made upon x-ray evidence which could sustain contradictory points of view with regard to interpretation.

Surgeon Vice-Admiral GASKELL said that a large number of cases of fracture occurred in the navy, though it was true that not much litigation arose in these cases. He was convinced that one of the most dangerous persons was the optimist who told the patient that all was well. If only the medical man would take a rather more pessimistic attitude he would prepare the patient and his friends for the bad results which occasionally followed even in the best practices. That was a point he always instilled into his junior officers. A too optimistic attitude also made the patient and his friends unwilling to call in a second opinion, which was one of the safeguards against any ensuing legal action. He thought that Professor Hey Groves's remarks ought to be widely circulated in the profession.

Mr R C FLEMING said that Professor Hey Groves's suggestion that the "accuser" might meet the "accused" before making any pronouncement which could be regarded as in the nature of criticism sounded very well in theory, but in practice it might be very difficult. He described the circumstances in a fairly recent case in which he himself was looked upon rather as an accuser, although he did not consider himself in that position. In that case he simply gave a proof of his evidence to both sides, and left it to whichever side liked to call him. Speaking of the Wood-Hill case, he said that in his view the points which settled that case were (1) the very grave divergence of evidence as to what directions had actually been given to the patient in hospital and after she had left hospital, and (2) the fact that some eight or ten weeks after the fracture the practitioner, on request from the patient's husband, writing from memory, and without having seen the x-ray picture, indicated on a diagram the site of the fracture, which proved to be erroneous. The speaker thought that medical practitioners ought to keep the most careful notes of their fracture and other cases, how they had been treated, and what instructions had been given to the patients.

Mr DONALD ARMOUR said that as long as human nature remained what it was, doctors would be found, some on one side and some on the other, and certain doctors, not content with being witnesses, would become advocates as well. One case in which he himself had been involved was a Colles's fracture referred to him at hospital by a medical practitioner. There was obvious malunion. Some weeks afterwards he discovered that the patient was bringing an action for damages against the medical man concerned originally in the case. The patient had said nothing to

the second doctor whom she had consulted. The speaker, having operated on her, was asked to give evidence on her side. He refused to do so, and being called into court he refused to furnish a proof of his evidence to either side, and told the Lord Chief Justice, before whom the case was heard, that he attended on subpoena and had refused the proof of his evidence to both parties. The judge protected him, and would not allow him to be made a witness for either the plaintiff or the defendant. In another case, heard before Mr Justice Roche, the circumstances were very similar, and the judge acted in just the same way.

Dr L. M. CALLENDER related a case in which a young lady, who until her marriage had been a patient of his own, was thrown from her horse in the hunting field. A local practitioner attended her, took her in an ambulance to the local hospital, and had x-ray photographs taken. The x-ray pictures were eventually brought to the speaker by the parents of the lady, with the statement that she had fractured the sixth and seventh ribs and dislocated one of the bones of the pelvis. But the x-ray pictures were so hopelessly bad that nothing at all could be gathered from them. Later it was shown that there had been a fracture of the twelfth rib only. It appeared that the x-ray pictures had been taken by a local chemist with an ancient apparatus and the exposure was so long that respiratory movements had interfered with the clearness of the result. The possession of ancient x-ray apparatus might be a real source of danger.

Mr H. A. T. FAIRBANK said that the first obligation of the profession was to do the best for the patient. If it came to a question of criticizing the procedure of the practitioner who had first treated the case, this seemed to be unavoidable if the second man was to do his duty to the case. The only thing he could do was to refuse definitely to criticize his predecessor without having had a talk with him, because the second practitioner could not know what difficulties the case had presented at the beginning. With regard to the suggestion to have an assessor, he thought it an excellent idea.

Mr WARREN LOW remarked that those who had been practising for the last thirty years realized what an extraordinary boon the x-rays had been, but while excellent servants they were hard masters, and it was well not to be slaves to the x-ray habit. There should be no delay in dealing with a fracture through waiting for the radiologist. The rays were perhaps more useful after the fracture had been dealt with than they were before. The public ought to realize that surgeons were not always successful in dealing with fractures at the first attempt. He thought the first two of Professor Hey Groves's suggestions rather impracticable, and as to the third—the assessor—it was true that an assessor sat with a county court judge, but the judge was not obliged to ask his opinion or to follow it.

Dr REDMOND ROCHE mentioned two recent cases in his own family in which the x-ray picture had been misleading. He thought the profession was allowing itself to be led by the nose to some extent in this matter by assenting to the proposition so generally laid down that x-rays were the absolutely essential to diagnosis. What he thought to be a slighting reference had been made by one of the speakers to the "ordinary surgeon." But it was not only ordinary surgeons who were at fault, he gave an instance of an error of which a one-time vice-president of the Royal College was guilty.

Mr W. F. TANNER pleaded for a revision of the nomenclature. The terms "closed" and "open" fracture should be used instead of "simple" and "compound."

Dr ANTHONY FERRIS said that if the second of Professor Hey Groves's suggestions were taken, and "accused" and "accuser" met in consultation, the evidence of both in court would carry much less weight and would be looked upon as suspect from the beginning. As to the assessor he mentioned a case which turned upon neurological evidence in which the judge ruled against the five neurologist witnesses, adding that his assessor quite agreed with him. It transpired that the assessor was a surgeon.

Mr H. W. CARSON said that the public was educated to believe that in all fractures a perfect functional result

could be secured, in the hands of the very best practitioners in orthopaedic surgery this was not always possible. The public was also being misled as to the value and importance of the x-ray photograph, which was difficult to take and more difficult to read, especially if it had been taken early in the case and was compared with the appearance presented weeks or months afterwards.

Professor HEY GROVES, in reply, said that in speaking of an "accuser" he had in mind those cases—roughly 10 per cent of the whole—in which a medical practitioner had allowed himself definitely to impugn the conduct of a colleague in a way he would not have done if he had been informed of the facts beforehand by consultation.

Dr JAMES NEAL still maintained that the x-ray examination was essential in any case of doubtful diagnosis. He would not suggest that a medical man should invariably rely mainly upon an x-ray examination for his diagnosis, but he thought that even a negative x-ray result would be a very good factor in defence, assuming that the photograph had been taken by a good radiologist and had been rightly interpreted. It had a certain objective value when produced in court.

SURGICAL EDUCATION AND SURGICAL PRACTICE IN THE FUTURE

At the meeting of the Section of Surgery of the Royal Society of Medicine on November 7th Sir HOLBURT WARING, the now president of the Section, delivered his address from the chair.

Sir Holburt Waring explained that his purpose was to suggest some points in connexion with surgical education and practice in the future. Dealing first with the basic sciences—chemistry, physics, and biology—in relation to surgical education, he said that since 1923 the medical curriculum had been lengthened by establishing a pre-registration examination in chemistry and physics. He was not sure that the change had been entirely advantageous. Chemistry and physics were now in many cases taught to future medical students in schools or colleges badly or inefficiently equipped for the purpose, and there had been many evasions or semi-evasions of the spirit of the General Medical Council's recommendations whereby this change was brought about. It was disadvantageous also because biology had been omitted from the pre-registration examination. It would be in the interests of medical education to add biology to this examination, and only to admit to such examination students who had completed courses in these three subjects, either under recognized teachers or in schools or colleges recognized for the purpose. The course in biology should also be modified so as to comprise general biological problems, and the present extensive "type" method of instruction should be considerably curtailed. If some rearrangement of the kind were made it would be easier for medical schools to carry out the Council's recommendation that the study of the basic sciences should be continued throughout the entire period of the students' curriculum. If this were done the heads of the departments of chemistry, physics, and biology could be utilized, first in teaching these subjects as applied to medicine and surgery, and then in many directions in connexion with pathology and diagnosis. At the present time it was rare for a biologist to be called upon to deal with the elucidation of a clinical or pathological problem in a hospital.

Methods of surgical education had been modified to a considerable extent during recent years by the increasing tendency in nearly all schools and hospitals to develop specialism. New special departments had been added in most hospitals with the result that the clinical facilities of a general surgeon had become limited in respect to the forms of surgical diseases admitted to his clinic and so made available for the surgical instruction of students.

Passing to the combination of teaching hospitals and Poor Law medical institutions, Sir Holburt Waring trusted that the discussions now proceeding might result in some satisfactory arrangement. Up to the present it had not been possible to utilize these institutions in the best

possible way, owing to vested interests on the one hand, and sentimental objections on the other. But he did not wish to see young students called upon to do work in connexion with these institutions either for nothing, or at a "sweated" rate of pay.

With regard to professional units, the advantages which had accrued from the appointment of a whole time professor of surgery had been chiefly along the lines of increased research on surgical subjects and the reorganization and general improvement of surgical teaching in the non-professional portions of the institution concerned. The non-professional units usually consisted of from 40 to 60 beds, with a personnel of a surgeon, an assistant surgeon or surgeon to out-patients, a registrar, and two resident officers. In the professional units more laboratory accommodation had been given and a larger personnel, which could be utilized for the purpose of diagnosis, treatment, research, and instruction. After pointing out some difficulties, chiefly arising from specialization, Sir Holburt Waring said that he was coming to the conclusion as regards professional units that these could best be utilized in surgical education by making them the organizing heads of the entire course of instruction on the surgical sides of the schools and hospitals concerned, giving preliminary courses to students before they commenced their clinical surgical work proper. They should be utilized also in organizing and carrying out research, and in the clinical education of students after they had passed through one of the non-professional surgical units. With regard to the non-professional units, the usual custom in most hospitals, especially in London, was for a student to spend six months as a surgical dresser. Instead of, as at present, limiting the student's work to one non-professional unit, it would be wise to enlarge the units by combining two together. If this were done, and time-tables rearranged, it might be possible to give to every student a much larger and more extensive course in practical surgery. In addition, courses of instruction in the special departments should be strictly limited to the subject-matter of those departments, and a specialist should not be allowed to try to extend his specialty into other parts of the body which might be considered to be connected with it directly or indirectly.

Rapidly reviewing some other subjects, Sir Holburt Waring said that he doubted whether the use of cinematograph films in surgical education, except in special cases presented any great advantages. The best use of the film was in connexion with many forms of fractures and dislocations. He was not sure how far the use of animals in the acquisition of technical experience could be justified in the education of the future surgeon. He could, by the use of animals, learn many details of surgical technique, but, on the other hand, conditions were somewhat different. Some work of this kind was done in the States, and under good teachers he thought it might be useful, but in this country at present, when the life of a dog was considered by many to be of more consequence than the possible alleviation or cure of disease in a sick human being, the use of animals for the instruction of students in surgical technique was out of the question.

The President then turned aside to discuss the admission of paying patients to hospital. It had been advocated that the provision of beds should be limited to the middle classes, the fixed payment to include the entire charges for accommodation, food, nursing, and surgical treatment, but, on the other hand, it was urged that if a voluntary hospital was to work a scheme of this kind satisfactorily the accommodation, nursing, and so forth should be provided for all classes of patients. He himself felt strongly that the latter was the best solution. Hospitals carrying out this provision would in most cases have to build for it was practically impossible satisfactorily to adapt the accommodation in a voluntary hospital, as it was known at the present time, for the needs of paying patients. One point would require careful deliberation before a decision was reached by any individual hospital adopting this system: this was the admission of patients by the administration on the recommendation of the staff, the financial details being left in the administration's hands. In his experience there was always a tendency to make use of the professional services

of the staff without giving thought to the financial remuneration which the circumstances of a case demanded. There should not, however, be any real difficulty in this respect if in connexion with the paying patients' department of a voluntary hospital there was established a combined board of representatives of the administration and of the professional staff. The utilization of a voluntary hospital for paying patients would make the latest methods of diagnosis and treatment available to all classes.

On the subject of radium and x-ray diagnosis and treatment, Sir Holburt Waring pleaded that in common fairness to all classes of the community the use of radium for treatment should be as readily obtained for paying patients as for the poor, and this could only be done under present conditions by the utilization of the special radium institutes and the radiological departments of large hospitals.

Next he said a few words on the subject of private hospitals and nursing homes. These were for the most part private houses which had been converted into hospitals—a conversion which, in the majority of instances, was unsatisfactory. There were a few examples in London, and others in some of the larger provincial towns, where private hospitals had been specially built. In most of these, however, accommodation had only been provided for the patients, and had comprised rooms and an operation theatre. Every private hospital ought to have a well equipped pathological laboratory, an operation theatre, and an x-ray installation for investigation and also for treatment, provision ought also to be made for light treatment, and in some special cases for physical exercises. It might be said that this would be too expensive to prove an economic success, but he could not agree. If the hospitals were made sufficiently large and well equipped, and provided accommodation for different classes of paying patients, he felt a surer that they would justify themselves commercially.

Finally he touched on the subject of "economic" and "uneconomic" operations, remarking that from an economic point of view surgeons were not always a valuable asset to the country. They performed operations which resulted in the prolongation of life when the lengthened life was an economic loss to the State and often of no pleasurable value to the patient. He referred to such operations as gastrostomy for advanced cases of carcinoma of the oesophagus. After the operation had been successfully done, and the patient taught to feed himself, he returned to his home only to linger and suffer, with no pleasure in life, and a cause of constant anxiety and trouble to his friends. On the subject of surgical operations to prevent the propagation of the unfit a whole evening might be spent in discussion. He suggested that at a later date the Section of Surgery might unite for a combined discussion with the alienists.

Mr W McANAM EOCLES said that the teaching of the basic sciences—chemistry, physics, and biology—in the public schools was never quite satisfactory because they were not taught with a view to the subsequent study of medicine. If it were possible for the teachers to get together and draw up some line of teaching which could filter down to the various schools and give correlation and direction to these subjects it would be of real assistance. He had been a little surprised that Sir Holburt Waring had not spoken about anatomy and physiology. He was in doubt as to how far anatomy, even yet, was really being taught with a view to subsequent clinical practice. The reason why it had been arranged that the three basic sciences should be taught before the student went to the medical school was that more time might be available, not only for clinical subjects, but for a thorough grounding in anatomy and physiology as applied to future clinical practice. As for surgical education proper, there was no doubt that the real basis for surgical education was contact with surgical patients. Long hours spent in the theatres might beyond certain limits, be more or less wasted time, and the student might be better employed in studying cases at close quarters—such as a hydrocele and the method of tapping—than in watching operations from a distance.

Mr V WARREN LOW remarked that those who proposed to enter medicine were now required, after a very good

school education, to devote five years before passing a "bread-and-butter" examination, and even when they came up for this examination about 40 per cent of them were "ploughed." There must be something wrong with the curriculum or with the public requirements when this was possible. Perhaps too much detail was demanded in the earlier stages of a medical student's life. More time might advantageously be spent on principles. Having learned the principles of chemistry, physics, and biology, could not a system be arranged whereby the details would be brought to the student's notice as he went through his clinical career? He might be able to learn the details of his physics more quickly while he was using his instruments. Students also might be brought into responsible relationships with patients at an earlier stage.

Dr GEORGE JONES, speaking on the relations of voluntary and municipal and Poor Law hospitals, said that in London, should the borough councils combine with the Poor Law guardians, they would find themselves in a very strong position as against the London County Council with regard to medical services, and the combined authority might insist that the whole of the medical services of the area should be transferred to them—lock, stock, and barrel. At the present time the borough councils or their medical officers complained of a certain hampering of their work by such activities of the London County Council.

Mr R C ELMSTREE said that professorships in surgery had the disadvantage of taking their holders away from private practice, and private practice was of immense value to the teacher because it introduced him to a class of case in some respects more useful for teaching purposes than those he saw in hospital. With regard to specialism in surgical teaching, his own feeling was that the teaching of special subjects should be supervised by the professor of surgery. He had felt for a long time that the undergraduate received too much teaching in major surgery, also he recalled that in his own undergraduate days he saw too much of the teaching of one surgeon and too little of the teaching of other surgeons. It would be an excellent plan if in every medical school each surgeon had at least one class a week open only to students who did not belong to his unit. As for the method of teaching the technique of surgery when the student was a young house-surgeon he himself might sometimes be allowed to operate while the teaching surgeon acted as his assistant. That was a very good way of teaching.

Mr ERIC PEARCE GOULD said that what it was desirable to ensure was a large number of post-graduate appointments for men who were intending to take up surgery as their life-work. As for the teaching of preliminary subjects, this was primarily of value as giving a man an insight into scientific principles and possibly an opportunity of discovering whether or not he had a facility for the study of science. Mr R P ROWLANDS remarked that every effort to shorten the curriculum appeared to result in lengthening it. He felt that there was some danger of over-specialism, not so much perhaps from the educational point of view as from others. At Giv's they were not keen on professorial units, holding rather that all units should be coequal. Moreover, to divorce the professor from private practice was a bad thing from the point of view of his own teaching capacity.

Mr MAX PAGE thought it economically impossible for a man to give more than five—or at the very most, more than six—years to his medical education. That must be accepted on a comparison of medicine with other professions. He thought there would have to be a students' entrance examination of a sterner character to eliminate in advance a number of those who were obviously unfitted for medicine, and who accounted for some part of the 40 per cent of "ploughs" mentioned by Mr Warren Low. Dr JOHN GIX said that when he himself had passed through hospital he felt that he had seen an enormous number of major operations, but in the ordinary work of the general practitioner he realized that something else was wanted. When men now talked to him about going in for medicine he always advised them to study the beginnings of things, to get to know the smaller things, those earlier stages of disease which were not often seen in hospital,

those chronic cases which were mostly seen in infirmaries, and to make themselves proficient in operations such as tonsillectomy, the passing of catheters, and so on, which fell to the general practitioner's lot.

ANTE-NATAL CARE IN GENERAL PRACTICE

A MEETING of the Newcastle-upon-Tyne and Northern Counties Medical Society was held in the Royal Victoria Infirmary, Newcastle, on November 1st, with Dr W I HUME in the chair. After clinical demonstrations had been given in the out-patient department, a discussion on "Ante-natal care in general practice—its value as an aid and a policy," was opened by Mr H HARVEY EVERS.

Mr Harvey Evers said that he had two definite objectives—namely, to prove that ante-natal care was an essential adjunct to rational obstetrics, and that the bulk of this work must be done by the general practitioner if the service was to have its maximum efficiency. The elimination of eclampsia, the prompt treatment of venereal disease, the correction of malpresentations, the diagnosis and correct management of cases of disproportion, were all emphasized as the direct results of efficient ante-natal supervision. Stress was laid upon the advantages of induction of premature labour, in Mr Evers's experience, as a means of avoiding much difficulty. The speaker also showed the difference in the results of cases of placenta praevia where the patient was under supervision, as compared with those which were unsupervised. Moreover, demonstration of the fallacy that pregnancy and labour were normal physiological processes would be of great advantage to the patient and to the doctor, it would enable patients to see more clearly the need for supervision, and would make the medical man's position much more comfortable where complications or disorders occurred. Mr Evers thought that no woman should be allowed to come into labour without a previous examination by a doctor. The positions of the midwife and of the public ante-natal clinic were discussed and it was pointed out that the best work could not be done by a whole-time ante-natal officer, efficient supervision could only be given by someone in the active practice of obstetrics. The work must be done by the family doctor who would thus acquire full control of the maternity service. He would then be in a position to deal with his patients in a manner which he considered to be to their greatest advantage. The work was easy to learn, took little time to practise, and was welcomed by the patients, provided that vaginal examination was avoided, except where absolutely necessary.

Dr RUSSELL read a paper by Dr L M WELLS, discussing his experience of ante-natal work in private practice, and indicating its great advantages in saving lives of mothers and children, as well as in the prevention of a great deal of subsequent maternal morbidity. Dr Wells described his ordinary routine, and pointed out that the technical side of the work was easy to learn, took not more than three-quarters of an hour in each case over the whole period of the pregnancy, and was welcomed by all his patients. He emphasized the importance of a consultant's opinion in doubtful cases, and gave examples of the good results he had obtained thereby. He gave a summary of 156 cases from his own practice, and called attention to the large proportion of abnormalities and the great benefits derived from ante-natal methods.

Dr S WONTANNEON gave his views on the work in industrial practice, and was enthusiastic in his support of Mr Evers's remarks. He deplored the passage of obstetrics from the hands of the general practitioner, and agreed that there had been a great increase of abnormal cases in recent years. He submitted that the ante-natal clinic and the maternity hospitals should suffice for the very poor, and that for the insured class suitable provision should be made whereby the fees for ante-natal supervision would be guaranteed to the doctor. He preferred that in a normal case there should be a midwife only, rather than a doctor only, provided that the patients were examined ante-natally by a doctor. His routine was described and he asserted that his patients now accepted examination without any difficulty.

Reviews.

CARDIOVASCULAR DISEASES

THESE are special reasons for welcoming Sir HUMPHRY ROLLESTON'S Harveian Oration in the shape of a neat and handy volume.¹ As a record of the historical growth of our knowledge of cardiovascular diseases since Harvey's day it is singularly detailed and complete, and it will therefore be accepted as a standard of reference brought fully up to date. In addition, the text is accompanied by a widely collected bibliography, where the student of the future not less than his colleague of to-day, will find direction and help. And yet again, the volume form has admitted some chapters which the limits of time excluded from the Oration as delivered on St Luke's Day to the Royal College of Physicians of London. It is well, therefore, that so serviceable a contribution should be given in a complete, permanent, and readily accessible shape. The Oration, and a leading article on the subject, we published in our issue of October 20th.

INTRACRANIAL TUMOURS

THOSE who were fortunate enough to hear Sir JAMES PURVES STEWART'S presidential address to the Neurological Section of the Royal Society of Medicine in 1926 will welcome his book on *Intracranial Tumours and Some Errors in Their Diagnosis*² as providing them with a means of reviewing this clinical material at greater leisure than was possible during an hour's lecture.

The author opens with a description of what he calls the general signs of intracranial tumour, and then devotes a chapter to each of the principal anatomical divisions of the brain, giving an account of the localizing signs usually expected from tumours in these situations followed by a detailed account of several cases pertinent to the chapter. He does not claim to have made any novel observations, but, taken as the record of a careful and skilled observer's notes on cases in each of which the diagnosis was confirmed by operation or autopsy, this monograph is of great interest and value. The introduction is written with such disarming modesty that criticism is embarrassing. Each clinician who has elaborated his own method of examination will feel that the particulars given are in many cases incomplete in some important detail—this is bound to be so from the nature of individual experience and what the author has himself referred to as the personal factor. The frequency with which confident deductions as to the site of a tumour are falsified by subsequent events has led one eminent neurologist to remark that their localization is a sport and not a science. Probably all would agree that the most important differentiation to be made in practice is that between intracranial tumour and some other condition, rather than between tumours of differing intracranial site, and it is therefore to be regretted that the chapter on errors of diagnosis contains only four cases where this was in question.

The suggestion that epileptiform convulsions may be due to anaemia of the motor cortex (p. 7) does not tally with the fact correctly given (p. 4) that local cerebral anaemia causes loss of function and paralysis—unless, indeed, the author regards these as release phenomena due to the uninhibited discharge of lower level mechanisms. Again, when he says that in some cases "the increase of intracranial pressure is due to the blocking of the foramen magnum by a pressure cone formed by the prolapsed brain-stem and cerebellum" he is surely overlooking the fact that it is this increase of pressure which is the most common cause of spinal herniation of the intracranial contents, although a vicious circle may thereby be established causing an acceleration of the rise in pressure. These are however minor points in which the pathology does not rise to the level of the clinical observations set out in this monograph, and they do not materially affect its value.

² *Intracranial Tumours and Some Errors in Their Diagnosis*. By Sir James Purves-Stewart K.C.M.G. C.B. M.D., F.R.C.P. Oxford Medical Publications, London: Milford Oxford University Press (Demy 8vo. pp. xviii + 206. 61 figures. 12s. 6d. net.)

EXPERIMENTAL PHARMACOLOGY

In *Introduction to Experimental Pharmacology*,³ by SOLLMANN and HANZLIK, is an adaptation of Sollmann's *Laboratory Guide in Pharmacology*, a book that for many years has served as a valuable work of reference to teachers of this subject. The experimental courses therein described were very extensive, and in the present volume there has been a considerable reduction in the number of experiments, but those mentioned are described in greater detail.

The volume consists of two parts—chemical pharmacology and experimental pharmacodynamics. The first part presents a selection of experiments from the subjects of pharmacology, organic chemistry, and biochemistry. The second part describes a large number of animal experiments. The usual classical pharmacological experiments are included, and, in addition, a number of original experiments are described. The chapter on gastro-intestinal movement deserves special mention, and in particular an excellent method for the photography of intestinal peristalsis is given. The volume concludes with a series of appendices, the most important of which, comprising 30 pages, gives the doses for animals of all the most important drugs used in experimental pharmacology. This appendix was one of the most useful features of Sollmann's familiar textbook; it has been carefully revised and brought up to date, and will be found of the greatest value by all pharmacologists and physiologists. A new appendix has also been added giving the dilutions at which drugs act on isolated tissues.

This textbook will be found of the highest value as a work of reference by all teachers of pharmacology and physiology. It is not, however, well suited to the needs of the British student, because a considerable proportion of the subject-matter is devoted to the description of experiments on living animals, which cannot be performed by students in this country; moreover, the course described is far longer than could be carried through in the time allotted to experimental pharmacology in any university in this country.

RADIOGRAPHY IN GYNAECOLOGY

*L'Exploration Radiologique en Gynécologie*⁴ is the title of an interesting book, the work of Dr. CLAUDE BÉCLÈRE of Paris. The first chapter deals shortly with the use of "pneumoperitoneum" in gynaecology, and there is a short reference to the method of injecting air through the uterus and Fallopian tubes, but the main part of this book is based upon the author's own experience in cases in which an opaque material—iodipin—was injected into the uterus and tubes for diagnostic purposes. Following a historical reference, the full technique, with the author's modifications, is described in detail. The rest is profusely illustrated with radiographs of cases after injection, accompanied by descriptive notes and comments. A comprehensive bibliography is added.

To those interested in the subject this book should prove both useful and instructive, the author writes in easy style, and everything is very much to the point, with a complete absence of padding. Apparently the whole ground is covered, and every condition in which such a method of examination can be useful is illustrated. We may add that it is very well printed on excellent paper, and the radiographs, about sixty in number, which show the finest technique, are beautifully reproduced.

AMERICAN MEDICAL BIOGRAPHY

To the admirable industry and esprit de corps of Professor HOWARD A. KELLY and Dr. WALTER L. BURRAGE the profession is much indebted for *The Dictionary of American Medical Biography: Lives of Eminent Physicians of the United States and Canada, from the Earliest Times*.⁵ It is the successor of *American Medical Biographies* (1920),

³ *An Introduction to Experimental Pharmacology*. By Torald Sollmann M.D. and Paul J. Hanzlik M.D. Philadelphia and London: W. B. Saunders Company, 1928. (6 x 8½, pp. 321. 3s. 6d. net.)

⁴ *L'Exploration Radiologique en Gynécologie*. Par Claude Béclère. Préface de Raymond Grégoire. Paris: Masson et Cie, 1928. (Med. 8vo., pp. 175. 61 figures. 45 fr. sans majoration.)

⁵ *Dictionary of American Medical Biography: Lives of Eminent Physicians of the United States and Canada from the Earliest Times*. By Howard A. Kelly M.D. LL.D. and Walter L. Burrage A.M. M.D. New York and London: D. Appleton and Co., 1928. (Sup. roy. 8vo., pp. xxx + 1394. £2 10s.)

by the same authors, which was founded on Professor Kelly's (*Cyclopedia of American Medical Biography* (two volumes, 1912), this in its turn being constructed on the same lines as the *Medical Biography*, published in 1828 by James Thacher (1754-1844), who in the present volume is described as "standing at the head of the list of medical historians in this country." The dictionary contains 2,049 biographies, as compared with 1,948 in the 1920 edition, there are about 300 new entries some of the old ones having been cut down to the name with a reference to the former edition. The two editors are responsible for an amazing number of lives, but to such an undertaking there are naturally many other contributors, such as C. L. Dana, W. B. Cannon, L. I. Cordell, Sir W. Osler, J. R. Packard, L. S. Pilcher, John Howard, who wrote on Emmett Holt, C. R. Bardeen, and J. F. Fulton now of Magdalen College Oxford, who supplies the lives of J. G. Adams and A. E. Brill, well known as the describer of the endemic form of typhus eponymously called Brill's disease. Some of the lives are unsigned, such as that of Surgeon General W. C. Gorgas who have no reason at all to suggest it, but possibly this is concealed the work of a Government official and a great medical historian who would naturally be expected to contribute to this dictionary. The accounts of a number of pioneer women doctors such as the sisters Elizabeth and Emily Blackwell, Rachel L. Bodley, Lucy Serall, and Mary Harris Thompson, the first woman who specialized in surgery, are signed by Alfreda B. Withington. Professor Howard Kelly writes the notices of his old colleague Sir William Osler, of Theodore C. Janeway of the Johns Hopkins, and of John McCrae of Montreal. He also writes on the famous W. C. Wells, the author of "The Essay on Dew" who was born of Scottish parents in Charleston, South Carolina, but is also claimed by our country, and naturally is noticed in the *Dictionary of National Biography*.

This volume, the outcome of twenty years' work and, as the preface says, "years of delightful occupation browsing in old volumes, writing to, and hearing from, interested colleagues," brings the biographies down to the beginning of 1927. It includes medical men of all kinds, not, as the title "Lives of Eminent Physicians of the United States and Canada" might suggest to some British ears, those only who practise pure physic, but medical men who have abandoned medicine and gained distinction in science and other fields. It is an absolutely necessary guide to all interested in the medical history of the English speaking New World.

GERMAN SPAS

MR S. L. BEUSAN, having visited Bad Nauheim in search of health, proceeded to visit other German spas by way of holiday. In *Some German Spas** he records for English benefit his impressions of certain health resorts, being convinced that "the common interests of both countries would be best served, and the chances of another European war most effectively lessened, by the re-establishment of a close and ultimately friendly intercourse between the two nations." Mr Beusman may be thought by some to suffer from a serious disability as a student of German waters: he admits that he is "one of those foolish people who take no alcohol in any shape or form." No man, it has been said, can become a connoisseur in these waters without the antidote of the vintages of the Rhine the Moselle the Nahe, and the Ahr, on the beet of Munich. However, Mr Beusman seems to have derived pleasure as well as health from his tour, he describes pleasantly the attractions of each place that he visited he lays stress on the cheerfulness that pervades the spa from the early morning hymn to the extinction of the lights of the kursal and he admits the influence of the surroundings on the mind of the patient. As becomes a non-medical observer he does not attempt to enlarge upon the medicinal effects of water drinking and bathing, though he seems to think the latter procedure the more important. But he describes in glowing terms the beauty of the spots in which the springs bubble forth: he is duly impressed

by the somewhat garish luxury of Wiesbaden, but he prefers the peaceful surroundings of Wildungen. The book is illustrated with photographs of the spas and their surroundings, and there are chapters on some of the old towns and beauty spots within reach of the health seeker. The pleasing impression to be derived from Mr Beusman's book is the thoroughness with which the German organizes his health resorts. Further evidence of the German thoroughness in this respect is afforded by the comprehensive directory of German spas. Following an alphabetical list of these places, in which reference is made to the forms of treatment available in each instance, there is an account by Dr Hirsch of Charlottenburg of the various medical indications for special hydrotherapeutical procedures. A list of medical practitioners at the different places is supplied, and there is also fuller description of various spas with many illustrations and details of the pastimes available.

BIOCHEMISTRY OF PLANT PRODUCTS

IN their preface to the fourth edition of the first volume of *An Introduction to the Chemistry of Plant Products*,* Drs P. HAAS and T. G. HILL explain that their work has been rendered difficult by the enormous recent expansion in the subject of biochemistry. This work first appeared in 1912 and was intended for the use of advanced students in botany. Since that date a huge literature on biochemistry has developed and the authors have had the difficult task of selecting the information which is of interest to students of botany. The volume under review deals with the organic constituents of plants, and a full account is given of the chemistry of the fats, alcohols, carbohydrates, and proteins of plants, and also of such special plant products as glucosides, tannins, alkaloids, and plant pigments. Other chapters are devoted to the special problems of enzyme action and the colloidal state. The greater part of the volume is devoted to a description of the organic chemistry of plant products, but the physiological significance of these products is also discussed. These notes on plant physiology are some of the most interesting things in the book, and their perusal impresses the reader with the power of plants to synthesize the most varied and complex chemical compounds, but at the same time he will be astonished to discover how little is known about the physiological significance of these compounds. This is especially true of the plant products used in medicine, such as the tannins, glucosides, and alkaloids. Indeed, it appears to be doubtful whether these substances which are so indispensable in medicine, are of any value to the plant that produces them. For example, it is suggested that the most valuable drugs known to medicine such as morphine and quinine, are merely waste products stored where their accumulation can do no harm to the plant. It is curious that human medicine should be dependent on accidental waste products. The authors have evidently taken great pains to bring their book up to date and are to be congratulated on their success in extracting the matter relevant to their purpose from the vast mass of biochemical literature.

NOTES ON BOOKS

THE British Social Hygiene Council has published in book form a report* of the proceedings of the Imperial Social Hygiene Congress held in London in October 1927. Perhaps the most important part of the report is that dealing with the welfare of seamen in ports. Surgeon Captain T. B. Shaw, professor of hygiene at the Royal Naval College, Greenwich, laid stress upon the importance of recreational training in the navy for maintaining a healthy morale amongst seamen, and Sir George Buchanan described the efforts that are being made at the International Health Office in Paris to ensure satisfactory treatment for the sailor suffering from venereal disease from port to port in all the large seaports of the world.

* *Deutscher Bäderkalender*. Herausgegeben vom Allgemeinen Deutschen Bäderverband E. V. Abteilung A. Redigiert von Prof. Dr. Weissbela. Mit einer Einführung von Ministerialdirektor Dr. R. Prof. Dr. Dietrich Berlin. Bader und Verkehr-Verlag G. m. b. H. 1928. (Demy 8vo pp. 623 illustrated.)

* *An Introduction to the Chemistry of Plant Products*. Vol. I. By Paul Haas, D.Sc. Ph.D. and T. G. Hill, D.Sc. V.R.C.S. Fourth edition. London: Longmans, Green and Co. Ltd. 1928. (Demy 8vo pp. xvi+550. 18s. net.)

* *Proceedings of the Imperial Social Hygiene Congress*. London: British Social Hygiene Council Inc. 1928. (Demy 8vo pp. 314.)

* *Some German Spas*. By S. L. Beusman. London: N. Douglas. 1928. (Demy 8vo pp. xi+160. Illustrated. 8s.)

Dr L. Carozzi of the International Labour Office spoke of the attempt which will be made at the Maritime Conference in 1929 to deal with the question of social insurance for the protection of seamen in case of sickness and possibly also in case of accident. Representatives at the conference from various Government departments, from the Dominions, Colonies, Protectorates and Mandated Territories described the problems they had met with in the control and treatment of venereal disease. In the section dealing with the administrative aspects of social hygiene Sir Walter Greaves Lord K.C. indicated the difficulties which arose in defining and dealing with solicitation. Whether the Home Secretary will succeed in clearing up these difficulties remains to be seen but Mr I. B. Turner was convinced that the condition of the streets when he first came to London had been very much improved by police action. He thought also that owing to relaxation of this action recently there had been some return to the state of affairs which existed when he first took part in the medical side of rescue work some fifty years ago.

The main theme of Dr SEJOURNE'S book¹⁰ on mitral stenosis in relation to the puerperal state is that while the ordinary methods of clinical examination are insufficient to show whether pregnancy in a case of mitral stenosis will be well borne or otherwise radiological examination gives more precise evidence as to the state of the heart, and that by noting the appearance and development of certain signs in the early stages of pregnancy, a definite prognosis may be made. The signs to which he attaches chief importance are auricular dilatation and changes in the hilar shadows interpreted as indicating stasis in the pulmonary veins. The book however, is lacking in detailed evidence to show the value of the methods adopted by the author and especially is there no evidence that radiological examination can provide earlier or more definite signs of the onset of heart failure than can examination of the superficial veins by the unaided eye.

The *Chemical Laboratory Manual*¹¹ of BOGERT is a companion to the same author's *Fundamentals of Chemistry*, which is a textbook for nurses and others. The laboratory manual gives directions for the practice of a number of experiments illustrating lessons set forth in the companion work. It is prepared with care and forethought for all that the student may lack, whether in tutorial supervision his own power of insight or even dexterity and would accordingly be particularly helpful to a student working alone. The first experiments described are those demonstrative of the most elementary facts of chemistry. Then follow experiments on carbohydrates, fats and proteins, leading to a knowledge of their physiological relationships, and a few experiments on blood and urine. It is a very practical little book.

Dr HENRI THIBAUT'S thesis on the necessity for adapting the anti-tuberculous armamentarium to the current conception of the evolution of tuberculosis¹² is partly a condemnation of our present methods of dealing with the tuberculosis problem, and partly a suggestion for mobilizing our available forces to the best possible advantage. His general argument is that the majority of cases of pulmonary tuberculosis are not insidious in their onset, and that, as febrile patients are generally excluded from sanatorium treatment, the cases that are actually admitted must be either febrile cases which have reached an intermittent phase or cases that are probably not tuberculous at all. What is really necessary is immediate treatment for the early febrile case. He therefore suggests converting most of the present sanatoriums into sanatorium hospitals, and sending to these the early cases with acute onset encountered at the dispensary or the hospital. The type of patient who at present occupies the sanatoriums he would transfer to fresh sanatoriums, constructed at slight expense from country property, or else built up of movable shelters of the Papworth type. The conditions in France are clearly different from those in this country, nevertheless, the problem is essentially the same, and most tuberculosis workers will find the author's thesis of considerable interest.

Unlike radiotherapy, which almost from its beginning has had a physical experimental basis, radiography has remained very largely empirical. Dr W. BRONKHORST, in a study of contrast and sharpness as present in the x-ray image,¹³ has

¹⁰ *Le Rétrécissement Mitral dans les Rapports avec l'Etat Puerpéral* par J. Séjourné. Paris: G. Doin et Cie, 1928. (64 x 94) pp iv + 156. 22 figures. 4 plates. 25 fr.

¹¹ *Chemical Laboratory Manual*. By L. Jean Bogert. Ph.D. Philadelphia: P. Allan and Co. Ltd. 1928. (Demy) Bro. pp 142. 23 figures. 7s. 6d. net.

¹² *La Nécessité d'Adapter l'Armement Antituberculeux à la Conception Actuelle de l'Évolution de la Tuberculose*. Par Dr Henri Thibault. Paris: L'Expansion Scientifique Française. (64 x 94) pp 134.

¹³ *Kontrast und Schärfe*. Von Dr. W. Bronkhorst. Aus dem Loewen Fortschritt Nr. 15. Leipzig: G. 4 plates. 30 charts. 21.15.

therefore tried to establish an experimental basis for the different factors influencing the production of the skiagram, and to systematize them. The first part of the book deals with the influence exercised by the intensity of radiation, the quality of the rays, the thickness of the absorbing and diffusing tissues, and the results following the use of intensifying screens and the Potter-Bucky diaphragm are considered. The second part is concerned with the factors which govern the sharpness of the x-ray image and in particular the focus characteristics of the x-ray tube. Much careful research is incorporated in this study which is undoubtedly a valuable contribution to the science of radiology. Perusal of the book is by no means easy, one difficulty being the constant need of reference to charts, of which there are thirty, these are printed on separate sheets of flimsy paper and are placed in a special envelope attached to the cover of the book.

Students of social history and of medical criminal procedure, as well as those who are attracted by the grimmer side of life will find much of interest in *A Hangman's Diary*¹⁴. This volume, translated from the German by Mr C. CALVERT and Mr A. W. CRUICK, contains the journal of Franz Schmidt, public executioner of Nuremberg from 1573 to 1617, in the course of which period he put to death between three and four hundred persons. Details regarding the offences and executions are given from Schmidt's diary for each execution and for some of the minor bodily punishments carried out by him. Mr Calvert, in his valuable essay on the judicial methods and customs of the time, notes that many of the executioner's craft practised surgery of a sort and also carried on a ghastly traffic in severed hands, human skin, and similar objects which were valued for the purposes of magic and medicine. Schmidt himself it appears was held in high repute as a surgeon, possessing a better knowledge of the human body than most physicians of his day, this knowledge, as his journal records, he gained by dissecting the bodies of some of those whom he had executed.

Lieut. Colonel T. R. ST. JOHNSTON, the author of *A Wet Indian Pepper Pot*¹⁵ is the administrator of St. Kitts Nevis, in the Leeward Islands, a barrister at law, a medical practitioner and the writer of several anthropological works on native races of the Pacific. His latest book is designed not only to entertain, but also to awaken an interest in the West Indies and their people. The thirteen stories which he has written are primarily studies of native types—some figures of comedy and others grimly tragic, but all treated with sympathy and fidelity. This volume which is richly illustrated with character sketches in colour by Miss Eva Wilkin, should appeal equally to the general reader, the prospective visitor to the islands, or the stay at home tourist who appreciates an exotic flavour in his reading. Mr L. S. AMERY, Secretary of State for the Dominions and Colonies, contributes a preface.

¹⁴ *A Hangman's Diary*. Edited with an introduction by Ulbrecht Keller and translated by C. Calvert, B.A. Lond. and A. W. Cruick. M.A. Oxon. With an introductory essay by C. Calvert. London: P. Allan and Co. Ltd. 1928. (Demy) Bro. pp vii + 250. 8 plates. 10s. 6d. net.

¹⁵ *A Wet Indian Pepper Pot*. By T. R. St. Johnston. London: P. Allan and Co. Ltd. 1928. (6½ x 8½) pp xlii + 194. 13 plates. 10s. 6d. net.

PREPARATIONS AND APPLIANCES

TONSIL HOLDING VULSELLUM FORCEPS

MR C. A. SCOTT RIDOUT M.S., F.R.C.S. (Southsea) writes: Having had considerable difficulty with the clip of other tonsil holding forceps made so as to allow a guillotine or snare to be passed over them whilst holding the tonsil I have had made for me a type of cross action spring vulsellum forceps

which needs no clip, and over which a guillotine can easily be passed while the tonsil is pulled out of its bed. In practice I have found this instrument to work well, provided the spring is sufficiently strong. There being no clip to get out of order, the instrument is simpler in its action than the types previously used. I use this pattern, as illustrated, in both my hospital and my private practice. The instrument is made by Messrs. Allen and Hanburys, Ltd.

INJECTION TREATMENT OF VARICOSE VEINS

Messrs Burroughs Wellcome and Co. have placed on the market hypodermic quinine and urethane for the treatment of varicose veins by the injection of sclerosing solutions. This solution consists of quinine hydrochloride 0.25 gram and urethane 0.13 gram in 2 ccm of sterile distilled water, issued in hermetically sealed glass containers ready for immediate use.

SATURDAY, NOVEMBER 17TH, 1928.

MENTAL HEALTH AND DISEASE.

THE reactions of individuals to life are infinite in their variety, and for this reason, where disorders of behaviour are concerned, it is difficult to say when a person should be described as normal and when as psychopathic, neurotic, or psychotic. Who, for instance, would be disposed to state definitely when an individual of the cyclothymic type—the subject at one time of over activity and at another of depression—had reached a condition at which he had overstepped the boundary between health and disease? Many such personality types are able to accomplish a vast amount of useful and constructive work in a condition which the psychiatrist would recognize as one of mild mania and no surprise would be felt if it were found that this "press of activity" was liable to be followed by one of inadequacy, depression, and inability to do other than the merest routine work. Similar gradations between health and disease are observed in general medicine though here the fluctuations are not so apparent since the social reaction is not involved. It is now generally recognized that the living organism functions according to the same fundamental laws in both health and disease, and for this reason medicine cannot be divorced from physiology, nor psychiatry from psychology. Disease is a modality or variant of vital activity; it is the manner in which the organism reacts under certain conditions.

Every medical practitioner is aware that an understanding of disease cannot be gained without a knowledge of normal physiology. Conversely, the study of disease enriches our knowledge of the reactions in health. Thus much of our knowledge of the structure and functions of the nervous system has been derived from the study of pathological conditions. Similar sequences have occurred in the sphere of psychology and psychiatry. Starting from the study of mental disorders such clinicians as Freud, Jung, and Adler have been able to throw light on the mental reactions of normal people and though the theories of these psychopathologists are contradictory, and have not been accepted in detail by psychologists they have certainly vitalized psychology, influenced its development and brought it into relation with the facts of human life. It is only within recent years that the converse of this could be said—namely, that the psychologist had provided a groundwork, analogous to that of physiology, which could be applied in some measure to abnormal psychology. Formerly the academic psychologist was occupied in the main with introspective studies of the content of consciousness and ignored the fact that action was determined in a large measure by influences which lay outside the realm of focal consciousness, and which were unknown to the actor himself. It was therefore a revolution in scholastic psychology when Dr. William McDougall defined the one time science of consciousness as the science of behaviour. This gave a new orientation to psychology because it showed that this science is concerned with the human being in action, and not

merely with the inner world of ideas which are not open to direct observation. In a later work the same writer provided the student with a comprehensive textbook of psychology, and this was followed by a supplementary volume on abnormal psychology. Thus we have what is perhaps the first attempt to outline the fundamental principles of normal psychology in terms which are capable of being applied to abnormal psychology.

In his preface to the book on abnormal psychology¹ Dr. McDougall states that he wishes this volume and the one dealing with normal psychology, which had preceded it, to be regarded as two parts of one book. He emphasizes the complementary nature of the two volumes, hoping that their conjunction may do some thing to bridge the gap between academic psychology and the study of the neuroses and psychoses. He draws attention also to the regrettable lack of harmony and consensus of opinion within the field of psychopathology, pointing out that this field is cultivated by a number of warring schools whose teachings are so widely different that to a layman they might hardly seem to be concerned with the same topics and the same problems. In view of this situation Dr. McDougall makes it one of his principal aims to bring together in one consistent scheme what seems the soundest and most fruitful in contemporary academic psychology and in the teaching of the various schools of abnormal psychology. His reference to the chaotic state of psychological teaching would appear to be fully justified. In his preliminary physiological studies the medical student has the choice of various textbooks, but all of these teach the same basic principles, have the same terminology, and provide the same unified body of knowledge. With such preliminary knowledge the student is well equipped to pursue his later studies in physical disease. The student of psychiatry is by no means in such a happy position. Nowhere can he find agreement in terminology, in definitions, or in fundamental assumptions. He may find it impossible if he has read a particular book, to discuss the problems of human behaviour with the student who has read another book, for the simple reason that the writers of these two books do not speak the same language, they envisage the same reality from an entirely different aspect. If he attempts to grasp the later developments of psychoanalytic theory which now betray a tendency to drift away from the immediate problems of the clinic, he may find himself unable to understand what he is reading at all. There is in the sphere of both psychology and psychopathology a serious need for clear definitions, simplification of terminology, and a preliminary statement of basic assumption.

We have suggested above that disease might be defined as the manner in which an organism reacts under certain conditions. The nature of these conditions is clearly the aim of medical research to discover. In some instances they are known in others they have not yet been elucidated. It is known, for instance, that the symptom-complex enteric fever is the physiological reaction to the invasion of the organism by a specific bacillus. In the realm of psychiatry the problem of causation is more complex than in that of general medicine because the former is concerned not merely with abnormal reactions of the organism but with those of the individual as a whole. The conditions responsible for psychotic states are probably numerous and in many morbid syndromes

¹ *An Outline of Abnormal Psychology*. By William McDougall M.B. F.R.S. London: Methuen and Co. Ltd. (15s. net.)

it is impossible to point to one condition which can be held accountable for the symptoms provoked. Dr McDougall lays considerable emphasis on the psychogenic factor, and few psychiatrists would be disposed to deny that the stresses of life exert some influence in the production of the psychoses and neuroses. It is more than doubtful, however, whether the biogenetic psychoses can be ascribed solely to functional distortions of the instinctive tendencies owing to the pressure of external life. A psychosis is probably due to a number of mutually interrelated factors, no one of which suffices to account for the total reality exhibited.

RECENT RESEARCH ON URTICARIA

DERMATOLOGISTS will be the first to admit the baffling nature of the problems that surround urticaria. The genesis of this common and troublesome eruption is always ascribed to some circulating toxin, of which the origin, in the majority of cases, remains obscure. It has been cured from time to time by a multitude of remedies, all of which are uncertain. Here, as elsewhere, the multiplicity of remedies is evidence of ignorance and inefficiency. Till recently very little light has been thrown upon urticaria by pathological research. It was demonstrated several years ago that the formation of the typical wheal is accompanied by a small called exudation through the capillary walls, in addition to an outpouring of more fluid. This, unfortunately, did not take us much further. Late, however, some progress has been made from at least two different angles. It is well known that sufferers from urticaria are often sensitive to special substances only. It has been found by Prausnitz and Küstner that this sensitiveness lies in the serum, because if the serum of a hypersensitive patient be injected into the skin of another individual, the skin around the site of the injection becomes sensitized to the same substances as affected the donor of the serum, and it was also discovered by A. and M. Walzer that the serum preserved this power of sensitization for some months after it was drawn off. On the other hand, Lewis and his co-workers have shown that the phenomena of the urticarial wheal may be reproduced with almost exact fidelity by the intradermic injection of histamine, and it now appears that the familiar wheal is produced by the liberation of a substance, not yet isolated, which Sir Thomas Lewis designates H substance, and which may be actually identical with histamine itself. Again, it is well known that paroxysmal haemoglobinuria is, in susceptible persons, brought on by exposure to cold; the same patient may or may not be liable to urticaria if the skin be exposed to cold, and, again, cold may excite urticaria in the exposed skin of an individual who never suffers from paroxysmal haemoglobinuria. Sir Thomas Lewis is now embarked on an interesting series of investigations, which so far tend to show that these phenomena are due to lysins of different kinds, haemolysin determining haemoglobinuria and a dermolysin determining urticaria. He has already confirmed the earlier results of Prausnitz and Küstner in the particular type of hypersensitiveness by showing that the serum of the patient in whom cold leads to urticaria, when injected into the skin, induces a local sensitization to cold with the production of urticaria in a normal individual.

On the other hand, the subject has been approached from the purely chemical aspect by Drs Barber and Oriel. They opened a discussion on urticaria at the Annual Meeting of the British Medical Association this year with an extremely interesting paper dealing

with the biochemistry of allergic conditions. Allergy is now understood to mean all forms of hyper-sensitiveness, whether congenital or acquired, and the brand of the reaction of a hyper-sensitive person may be borne by his cutaneous, respiratory, gastro-intestinal, or nervous system. It would take too long to give a list of the various forms of reaction, which will be found in their paper, but there is no doubt that the cutaneous reactions are the commonest, and of these urticaria is the most typical. Moreover, it is also certain that among patients who show evidence of cutaneous allergy there is very frequently involvement of other systems—for example, of the respiratory system, as shown by hay fever or asthma, or of the nervous system, as shown by migraine. And even if the urticarial or pruriginous patient be free from other allergic reactions, it is almost certain that there will be found examples of some of the other systemic manifestations among his immediate family. It appears probable, therefore, that in such families there must be a sort of inborn metabolic kink which renders the affected person sensitive or 'allergic' to various bodies or conditions. Barber and Oriel have applied themselves to the problem of finding out the nature of that inborn error. While it cannot yet be said that they have solved this problem, they have at least demonstrated certain peculiarities of metabolism characteristic of the allergic state, and especially of the allergic paroxysm or acute attack.

In the first place, allergic subjects often exhibit an abnormally high amino acid content in the blood even when they are free from active manifestations, and during the paroxysm it is always raised above the normal level. Another deviation from the normal noted by Barber and Oriel relates to the chlorides. It appears that the chlorides in the blood are contained partly in the serum and partly in the corpuscles. In allergic individuals, especially during the attacks, the chlorides contained in the corpuscles are much diminished, while those in the serum remain unaltered. Again, in allergic patients the urates are commonly precipitated from the urine very readily. Such precipitation is a phenomenon that has attracted attention since the beginnings of urinary analysis, and it has always been supposed to depend upon the concentration and acidity of the urine. It now seems that these factors are of subsidiary importance; it is true that precipitation occurs only in acid urines, but even in strongly acid urines the urates often remain in solution. The secondary importance of concentration is shown by the fact that, while urates may be precipitated although present only in small quantity, in other instances large amounts are held in solution. The decisive factor in maintaining the solubility of urates appears to be dependent on the colloid state of the urine—a state which can be tested by taking the gold count. Another curious feature which Barber and Oriel have detected in urine from these patients is what they designate the 'ether reaction'. After the addition of a few drops of 25 per cent sulphuric acid and ether, followed by vigorous shaking the ether becomes so opaque and frothy that the test tube can be inverted without losing the contents. The significance of this reaction remains obscure, but it is interesting to note that it is often found in patients with cardiac failure, and the authors think it may depend upon a change in the colloid state of the urine. As regards the reaction of the urine in these patients, the general rule is that, while just before and during an acute attack the acidity of the urine remains high, as the attack proceeds the acidity falls, and occasionally the

urine becomes strongly alkaline with deposition of phosphates, and at the same time there is diuresis. Another interesting point is that the ammonia excretion also rises, although the acidity falls, during an acute attack.

The question that immediately presents itself after considering the work of these two complementary sets of observations is, How can they be linked together? Can the lysins, whether dermolysin or haemolysin, which physiological tests have revealed in the serum of urticarial patients, be made to correspond with any of the chemical abnormalities demonstrated by Barber and Oriel? One of the unsatisfactory features of haematological research is the constant manufacture of names which merely express physiological properties never as yet identified with definite chemical compounds. What are the antigens, complements, precipitins, agglutinins, and so on, of which it is the fashion to talk so glibly? We know to some extent what they can do, but we have no idea what they are. The determination of the chemical basis of these bodies is one of the urgent problems of pathological chemistry. To revert to the phenomena of urticaria the next step is the elucidation of the connexion between the dermolysin experimentally demonstrated and the amino acids, which are so chemically conspicuous in the blood of allergic patients and the H compound (whether histamine itself or an allied body) which is so closely associated with the production of the classical urticarial wheal. The fact that histamine is an amino compound may not be entirely without significance.

Undoubtedly much remains to be done but it may at least be claimed that for the first time the problem of urticaria has been attacked on lines which promise ultimate, even if still distant, success.

THE HISTORY OF THE ASSOCIATION

IN view of the approaching centenary of the British Medical Association in July, 1932, the Council has considered the advisability of preparing a history of the Association from its beginning as the Provincial Medical and Surgical Association up to the present time, and beyond it to the time of the centenary meeting. Most valuable historical sketches have already been published by the Association, from the pens of Mr. Russell Coombe, Dr. Guy Stephen, and the late Dr. J. C. McVail, but it is intended that the proposed volume shall give an account of the main activities of the Association and its Branches, as well as of the careers of those who have taken notable parts in its development and welfare. The duty of compiling such a record has been entrusted to Mr. E. Munhead Little, F.R.C.S., who will be very grateful for any information concerning past events that is not to be found in the medical journals of the last ninety-six years or will not be found in those of the four years to come. Information is particularly wanted as to the origin and development of the Branches, some of which, such as the North of England Branch, were founded very soon after the Provincial Association and were at first independent of it, but ended, as did the Eastern Medical and Surgical Association, by becoming Branches of it. But no information, or hint of where to find information, will come amiss, for it is obvious that in the course of ninety-six years much has been forgotten, and may only be recovered from the shelves of local libraries or the minute-books of local societies. Information or documents may be sent to the Medical Secretary, B.M.A. House, Tavistock Square, W.C.1, or to Mr. Munhead Little direct, at 32, Ashley Gardens, Westminster, S.W.1.

SOME MEDICAL WAR MEMORIES

WITH the passing of the years the celebration of Armistice Day grows no less sincere, and it is generally recognized now that there must be something of practical value to humanity in an annual revival of war memories. Of the making of books about the war there seems to be no end, but few of those lately issued reach the standard of *With a Women's Unit in Serbia, Salonika, and Sebastopol*.¹ In this volume Mrs. I. Emslie Hutton, who was assistant medical officer and pathologist to the Scottish Women's Hospital, sets forth a variety of incidents in the manner of the best kind of travel diary. A particularly vivid light is here thrown on Serbia in defeat and triumph. The story of the reoccupation of their country by the Serbians at last receives the attention it has awaited so long, and in simple language the author gives a moving impression of a most attractive people, who won the affection of such great women as Dr. Elsie Inglis, Mrs. Haverfield, and Mrs. Harley. From Serbia the scene moves to the Crimea, and the story of the ill-fated Crimean venture of General Wrangel is told with a restraint far more eloquent and convincing than any recrimination. Intimate touches illustrate laboratory work in Salonika and child welfare attempts in Sebastopol, the patient endurance and the helpfulness of refugees of many countries come often into the picture. Problems of hospital construction and of prophylactic campaigns appear in a setting which blends humour with pathos. It is well that after ten years of peace we should be reminded of the self-sacrifice and sympathy which the war evoked, and made to reflect that by these qualities war may some day be abolished. Such books as Dr. Hutton's are a practical contribution to the progress of humanity.

A COURSE IN DISEASES OF OLD AGE

THE New York Academy of Medicine has inaugurated a series of annual post-graduate courses, each of which will deal with one special medical topic. The first was held from October 1st to 13th, and the subject chosen on this occasion was "The problem of ageing and the diseases of old age." Clinics, clinical lectures, and demonstrations were arranged in more than thirty of the teaching hospitals of New York, which formed three groups, each providing a similar programme and thus obviating long journeys between different hospitals. Special attention was paid to such topics as "The prevention and postponement of normal senescence" including the early recognition and treatment of disturbances which initiate or accelerate the process. Among the numerous papers read may be mentioned "The pains, penalties, and prohibitions of old age," by Sir Farquhar Buzzard, Regius Professor of Medicine in the University of Oxford; "The ageing of the human brain," by Dr. F. Tilney, professor of neurology in Columbia University; "The mechanism of senescence," by Dr. Alexis Carrel of the Rockefeller Institute; "The treatment of arthritis deformans of the hip," by Professor V. Putti of Bologna, Italy; and "Angina pectoris," by Dr. Harlow Brooks, professor of clinical medicine in the University of New York. Dr. George Vincent, president of the Rockefeller Foundation, who gave an address insisted that doctors should regard themselves more as "trainers," and endeavour to keep aged people healthy, rather than as "healers," ministering to palpable ills. This would call for systematic attention to diet, exercise, personal hygiene, and medical examinations. Dr. L. I. Dublin, statistician of the Metropolitan Life Insurance Company, read a paper in which he said that, while it was true that more people were living to old age at present, this was mainly due to the fact that a greater number of lives were being saved at younger ages, the life

¹ *With a Women's Unit in Serbia, Salonika, and Sebastopol*. By I. Emslie Hutton M.D. London: Williams and Norgate, 1928. (Demy 8vo pp. 302. 13 plates. 12s. 6d. net.)

span itself had hardly been affected by better hygienic and economic conditions. A man had practically no more expectation of living to the age of 70 now than he had in 1840. Some eighty years ago a man at the age of 50 had an even chance of living to be 70, whereas in 1920 a man who was 50 years old had an even chance of living to be 71. The life span had remained almost stationary because the diseases which predominated in old age had not been brought under control. Cancer, for example, seemed to be increasing, while nephritis and cardiac diseases had only slightly declined. Dr Dublin doubted whether there was any great possibility of increasing the life span, but he believed that progress lay in the direction of conquering those diseases which were taking the heaviest toll of old age, in the adoption of preventive measures by the elderly, in periodical medical examinations, and in community hygiene. It may be added, however, that some of the recommendations are disputable, thus, the case against annual physical examinations of adults is deftly stated by Dr Logan Clondomer in the *American Mercury* for October under the heading "Health audits."

THE COLLEGE OF SURGEONS OF AUSTRALASIA

THE issue of the first number of the *Journal of the College of Surgeons of Australasia*, dated July, 1928, is a sign of the great activity of an institution which was founded as recently as February, 1927.¹ This College differs in several respects from the corresponding bodies in England, Scotland, and Ireland. Thus, while one of its prime objects is to bring together men of surgical competence and high character and to cultivate and maintain the highest principles of surgical practice and ethics among the surgeons of Australia and New Zealand, it does not conduct examinations in surgery, nor does it confer a registrable diploma. It is a voluntary organization, conferring its Fellowship solely by election. In order to foster the closest possible harmony with the British Medical Association in Australasia, the Credentials Committee of the Council is directed to inquire of the Association as to the eligibility of candidates for election as Fellows. At present there appears to be some disagreement about the interpretation of a phrase used in defining the aims of the College—"To educate the public to recognize that the practice of surgery demands adequate and special training." The Victorian Branch of the British Medical Association, while approving this object, holds that the registered medical practitioner has received such training, and that he is capable of differentiating clearly between those surgical cases that come legitimately within his province and those that demand specialist attention. It believes that it is futile to expect men deprived of regular surgical work to deal competently with the emergencies of general practice. Sir George Syme, President of the College, in a foreword to the first number of our new contemporary, expresses the hope that it may embody and preserve the best and most distinctive work of Australasian surgeons, and become the medium for communicating this to their colleagues in other countries. The contents of the opening issue include a suggested policy in outline for the improvement of Australasian hospitals, proposals for a scheme of post-graduate surgical training in Australasia, and a number of original articles on topics of general surgical interest.

THE VALUE OF SPA TREATMENT

DR KERR PRINGLE, the new president of the Balneological Section of the Royal Society of Medicine, devoted his annual address on November 8th to a reaffirmation of faith in spa treatment and a reminder that the leading mineral water stations of Great Britain are much more than centres of physiotherapy. He said that he

preferred to discuss some aspects of spa treatment, rather than rheumatism or gout, because in restricting discussions to specific diseases there was danger that the special point of view of the spa as a whole would be overlooked. Dr Pringle thought spas were mistaken in trying to explain the mode of action of the various ingredients of their mineral springs. Minute analytical tables did not convey much to the general practitioner, who, when he received a prospectus regarding a certain spa, and learned that its waters contained a certain number of grams of magnesium carbonate or sodium sulphate per litre, was apt to throw it into the waste paper basket. It would be better to enlarge on the clinical results, backed, of course, by investigations by the biochemist and physiologist. These clinical results had been forthcoming long before the precise constituents of the waters were known or could be expressed. Empiricism, here as elsewhere, had preceded exact science, which had confirmed the results of experience. Every Scotsman had known for generations that it was wise to take a little neat whisky with the haggis, and now the biochemist explained that the action of the whisky was to dissolve certain fats and make the haggis more digestible. On the outskirts of Edinburgh, in a small village called Liberton, there was a mineral spring which enjoyed considerable fame six centuries ago, especially in the treatment of skin diseases. This spring was now known to contain a certain mineral oil or petroleum in solution, which was thrown up in small masses to the surface. Here, then, was a mineralized water which for ages had been used empirically for skin diseases long before anything was known about the effect of liquid paraffin in removing the scales in desquamating conditions. Dr Pringle thought it rather unwise to attempt to explain specifically how each spring produced clinical results, it would be better to confine the description to the clinical results produced. The loss of individuality by spas was a still more important matter. Bath was famous for its natural mineral water, and Harrogate for its sulphur wells, and both these spas made their reputation through their waters, not by the introduction of many different forms of hydrological appliances and ancillary electrical treatments with which spas were apt to mask their individuality and character—an individuality derived from the nature of their waters, their climate, their altitude, and other factors. More reliance should be placed on the particular methods of treatment by the local waters. The spa physician sometimes forgot that the patient was sent to the spa for balneological treatment, and that he could usually get electrical treatment at his own home. Mineral springs should be regarded, not as the property of individuals or local bodies, but as national assets, and the State should assume a certain amount of control over them, allowing the local authorities to levy a "kur tax" in return. It might construct a ring fence three, six, or twelve miles round each spa, thus forming rest areas, within which factory chimneys might not belch, motor cars make no unseemly noises, and no cheap commercial distractions would interfere with the routine of treatment. Finally, Dr Kerr Pringle pointed out how little was really known about the numerous springs of this country. The advertisements of Harrogate, he said, were based on the number and variety of its mineral waters, yet the old sulphur well was practically the only one that Harrogate physicians knew anything about. They had more or less ignored the others, any one of which would have given a reputation to a mineral water station. Cheltenham had four excellent springs, regarding the use of which very little was known, and the same applied to Leamington. In the course of some brief discussion, Dr F. G. Thomson of Bath agreed that spa advocates had tried to do too much. There was a certain element of scepticism among the medical profession generally as to the methods and

¹ See *British Medical Journal* April 30th, 1927 p. 511.

effects of spa treatment, and the spa physicians had tried to explain in terms of chemistry or physiochemistry how these results were brought about, instead of contenting themselves with the fact that they were produced

WHEN THE PROFESSION VOTES

A CLOSER study of the result of the voting in the recent election of two direct representatives for England and Wales to the General Medical Council reveals some points of interest. We announced in the last issue (p 860) the return of Dr E K Le Fleming and Dr J W Bone, the candidates supported by the British Medical Association. The number of votes recorded on their behalf, well over 11,000 for each, falls only just below the unprecedented total recorded for Dr Brackenbury, who headed the poll at the previous election in 1924, when four representatives were returned, it must be borne in mind, however, that the electorate has increased by about 3,600 since then. The margin between the votes received by the second successful candidate and the first unsuccessful candidate on this occasion is also larger by 1,000 than that which separated the last of the four successful candidates and the first of the unsuccessful at the previous election. A less satisfactory feature is the proportion of the electorate—slightly more than one-half—who failed to record their votes. The percentage voting at the elections of direct representatives has shown a more or less steady fall ever since the first of such elections in 1886. On that first occasion, when the electorate in England and Wales numbered only 18,074—not much more than half its present figure—no less than 74 per cent of the possible votes were recorded. This was due, perhaps, not only to the novelty of the occasion, but to the fact that there were fourteen candidates for three seats. The three candidates supported by the Association were successful on that occasion also, and with ample majorities. In the subsequent elections, of which there have been as many as eleven, nothing like 74 per cent of the electorate has ever voted. In 1897, when Mr Victor Horsley (as he then was) beat Sir Walter Foster (afterwards Lord Ilkerton) by a narrow margin, the proportion voting touched 60 per cent, but in general it has been somewhere between 40 and 50 per cent. It is a figure which compares rather badly with the proportion of the general electorate voting in a parliamentary general election—75 per cent in 1924—and in a General Medical Council election the voter has only to go to the pillar-box and not to the polling booth. It surely cannot be argued that to the average medical man or woman the proceedings of the General Medical Council are less important than those of the House of Commons to the average citizen. A minor but more curious feature is the steady growth in the number of invalid votes. At the election of direct representatives in 1891—apparently the first at which this figure was recorded—these numbered 115, but the figure has grown until on this most recent occasion it reached 720. That one medical practitioner out of every two should not trouble to vote at all is perhaps less surprising than it is regrettable, but that one medical practitioner out of every twenty who does vote should fail to observe the rules, and thereby disfranchise himself or herself and waste time and labour and postage, is really astonishing. Why should 200 doctors be interested enough to vote at all and yet not interested enough to fasten their identification envelope in the way prescribed, or 271 others omit to sign their name, or 155 more send in their voting papers too late not to speak of 7 who posted empty envelopes? Invalid votes in a popular election are regarded as some index of illiteracy. That cannot be the case here. Is it absence of mind, or, more probably, impatience with all official instructions, even with the very simple ones issued with these voting papers, and a desire to "take them as read"?

ally, we may note that among the figures relating to this and previous elections, which have been most painstakingly gathered by the Registrar in a report to the English Branch Council, the cost of the election was £405, or roughly sixpence for each vote recorded.

LOCAL GOVERNMENT REFORM

THE text of the Local Government Bill, the longest and most complex placed before Parliament for several years, was issued this week, and the discussion of its provisions will constitute the main task before the House of Commons this session. A general outline of the scope of the proposed reforms was given in our issue of October 27th (p 765), and certain aspects of outstanding importance to the medical profession were discussed in our last issue in a leading article (p 854). The bill provides for the reform of the Poor Law and the system of roads administration, introduces extensive changes in the system of grants in aid of local services, and includes important changes in the law relating to town planning and to the registration of births, marriages, and deaths. It is proposed to transfer responsibility for the Poor Law service from the boards of guardians primarily to the county councils, each of these bodies will be required to set up a public assistance committee, under which subcommittees, to be known as guardians' committees, will be responsible for the actual administration of relief in their respective districts, the organization of institutional treatment will be the function of the public assistance committee, and this will be carried out on a county basis. It will be seen that this system offers the prospect of a considerable advance towards the unification of health services, and this should be encouraged also by the nature of the proposals relating to the acceleration of the appointment of whole-time medical officers of health to maternity and child welfare schemes, and to infectious disease hospitals, etc. The provisions of the bill relating to these subjects are practically the embodiment of the recommendations of the Royal Commission on Local Government, as outlined in the *Journal* of November 3rd (p 800). County councils, under the bill, will have conferred on them the powers possessed by local sanitary authorities to provide hospitals for the sick, and these powers are to be extended to cover maternity cases, the councils are also authorized to subscribe to voluntary hospitals. The financial provisions are extremely complex, and these seem likely to attract most of the attention while the bill is under discussion, although certain concessions have been made to meet the objections of local authorities. Included in the bill is a section incorporating the reforms in the registration system, which were the subject of a private member's bill introduced last session with the support of Dr Fremantle. It is intended to transfer responsibility for the registration of births, marriages, and deaths to the county and county borough councils, and gradually to convert the registration officers into salaried officers.

MEDICAL MEMBERS OF LOCAL PUBLIC BODIES

WE should like to be able to publish as complete a list as possible of medical men and women who are now serving on local public bodies in this country, and we invite the help of our readers in obtaining the necessary information. Medical members of the following bodies are asked to send brief particulars to this office on a postcard addressed to the Editor: County Councils, County Borough Councils, non-County Borough Councils, Urban District Councils, Rural District Councils, also medical co-opted members of Education Committees, Maternity and Child Welfare Committees, Mental Deficiency Committees, and medical members of Boards of Guardians. Such information is always useful, and it will be especially valuable during the coming year in view of approaching legislation.

Nova et Vetera.

JOHN DE VILLULA

In previous communications to the *British Medical Journal* I have given some account of two of the physicians to our early kings, in the persons of Nigellus, who has been held by some to have been the Conqueror's physician (the authority for this is the General Introduction to Domesday, by Sir Henry Ellis, he gives no reason for his statement, and it is only fair to say that Gilbert Maminot, Bishop of Lisieux, has much better claims to be considered the Conqueror's physician), and Grimbold, physician to Henry I.

John of Villula, or John of Tours as he is often called, was physician to William Rufus. Sir Francis Palgrave says of him that he "conjoined three faculties, a Clerk in orders, a Chancery clerk, and a physician, but the last capacity eclipsed all others. He was scarcely thought of otherwise than as a professor of the healing art. Therein he acquired a well deserved reputation, and earned an ample fortune. The episcopal historian of Bishops, speaking of John of Villula, informs us that he was *ex eorum genere quos empiricos hodie appellamus, non non literis medicis probatus*. Hence, probably, his success. He treated his patients by experience and common sense, instead of doing them according to Hippocrates and Avicenna. John de Villula went on prosperously, acted as though he considered himself not bound to obey the obsolete canons which censured his practice, took his fees, became a favourite at Court, the King's body-physician. Knowing that anything the King had to dispose of, could be bought, and seeking to employ his capital advantageously, he watched his opportunity for a good investment. This occurred upon the death of Giso, the old Bishop of Wells, which took place soon after the accession of Rufus, and he purchased the vacant incumbency."

John de Villula was appointed Bishop of Wells in 1088, and was consecrated in July of that year. The Council of London (1076) having sanctioned the principle of the movement of episcopal sees from villages to towns (of which the movement of the see from Dorchester on the Thames to Lincoln by Bishop Remigius is the best example), and Bath Abbey being vacant by the death of Alfsido, Rufus, in 1090, gave the post to John de Villula (who about this time bought the city of Bath from the King for the sum of £500) and authorized by a Royal Charter the removal of the see from Wells to Bath. The city had suffered much from incendiarism, and John de Villula rebuilt the Abbey Church, he also gave the convent an estate near Bath which he had purchased for £60. At Wells he destroyed the cloister, refectory, and dormitory, all of which had been built by his predecessor "to enable the canons to live according to the Lotharingian plan, and so forced them to live among the laity. With the materials, and on the site, he built himself a palace. John de Villula was present at the dedication of Salisbury Cathedral at Old Sarum in 1092, he was also present at the dedication of Battle Abbey in 1094. In 1102 he was present at the Synod of Westminster. It would appear that he was a skilful man of business, for he obtained confirmations of the Bath grant from Robert Courthoise as well as from Henry I.

John de Villula died in old age on December 29th, 1122, having been taken ill with pain in the heart after his Christmas dinner, or, as Symeon of Durham expresses it *Johannes Bathoniensis episcopus in die Natalis Domini, subito post prandium dolore cordis correptus sequente die moritur*. Perhaps he had an attack of angina pectoris. He was buried in the presbytery at Bath.

Of his patients we know little, but he certainly attended William de Carleph, Bishop of Durham, who in 1095 had been summoned to Windsor by the King, although he was ill at the time. He died on January 2nd, 1095 (O.S.).

In 1093 he was certainly in attendance on Rufus himself, who early in the year had been stricken with illness of an alarming character. Lying ill at Gloucester, he was urged by his attendants to forgive his debtors, to free his captives, and to restore freedom to the Church, particularly in the reinstatement of the Archbishop of Canterbury

Anselm was called in, ostensibly to give such spiritual aid as was possible to one who seemed to be on the point of death.

No one can doubt the courage of Rufus, it must have required considerable moral courage to have been an atheist in mediæval times, but he was so moved by the entreaties of those present that he gave way, and invited Anselm to undertake the Primacy. The scene is finely described by Palgrave. The sick king, propping himself on his enfeebled arm, pronounces the name hitherto so scorned and contemned "I choose the holy man Anselm." All present rejoiced, save one. Anselm himself wasaghast, and refused the dignity. But the King's attendants were not to be denied. Someone brought a pastoral staff, and they hurried Anselm to the bedside. His captors seized his right arm and turned the right hand towards the King. Anselm closed his fist and refused to open it. After an unseemly struggle, in which the poor old man was hurt, the pastoral staff was thrust into his hand. The bishops squeezed his hand in theirs, so that he could not drop the staff, and in spite of his cries of "*Nolo, nolo, non consentio*," he was deemed to have received investiture.

There is little more to say about John de Villula, save that he is credited with having built the enclosure round the chief mineral springs in Bath. He is said to have been of a courteous disposition and cheerful by nature. His investment of his capital in ecclesiastical preferment might suggest simony, but we must remember the age in which he lived, and not judge him too harshly in this respect.

The facts recorded here are mainly derived from the account of John de Villula in the *Dictionary of National Biography*, and from Sir Francis Palgrave's *History of Normandy and England*.

R. R. JAMES

A NATIONAL ASSOCIATION FOR COMBATING RHEUMATISM

A LARGELY attended meeting was held at the house of the Royal Society of Medicine on November 7th, to consider a proposal to transform the British Committee on Rheumatism, which has hitherto been a constituent of the International Society of Medical Hydrology, into an independent body for combating rheumatism.

SIR THOMAS HORDER, who occupied the chair, in introducing the proposal, said that he shared a very general repugnance to the multiplication of bodies which had no special function to perform. It would weaken rather than strengthen the national attack on rheumatism if the result of this movement were simply to constitute one more organization in a field in which several were already working. The object should be rather to link up existing efforts, and to co-ordinate and stimulate their work. In addition to the British Committee on Rheumatism, which it was now proposed should be dissolved and reconstituted, there was the Red Cross clinic in London for the treatment of rheumatic conditions, especially amongst the industrial classes, there was the work, still proceeding, of the British Medical Association in regard to the study of rheumatic disease in children, and at the various spas there were units which controlled and advised on research and therapeutics in general. If another body were to be set up it should be a body of such prestige that it could speak authoritatively and in the name of all the interests concerned with this pressing problem.

DR FORTESQUE FOX pointed out that this question was of more than academic interest. Probably no other group of diseases, with the exception of tropical diseases, was so disastrous in its effects upon public health and prosperity. Large numbers of people in various countries were working on the problem, on its social, industrial, and economic as well as its medical side, and what it was now proposed to do in Great Britain in setting up a national body had been done already in some Continental countries. He made it plain that the severance from the international society meant simply that it was desired to have a national organization on a broader basis than was possible for a committee of an international body charged only with the study of medical hydrology.

Dr ALISON GLOVER brought the good wishes of the Minister of Health, and gave a brief sketch of the activities already proceeding in the attack upon rheumatism. In regard to acute rheumatism, several public authorities already had large schemes in being, there was an extremely wide scheme at Birmingham, and in London there were already 230 beds specially allocated by the public authorities for acute rheumatism and chorea. There was reason to expect that in respect of both acute and chronic rheumatism London would be as well equipped as any city in the world. He instanced also the work of the British Medical Association and of the Medical Research Council.

A motion that a national association for combating rheumatic disease in Great Britain be formed was proposed by Mr W. A. APPLETON, the general secretary of the Federation of Trade Unions, and seconded by Dr C. W. BUCKLEY of Buxton. This was agreed to unanimously, as were resolutions that the provisional name of the new body should be the "National Association for Combating Rheumatism," and that membership should be open to all, medical and lay, on payment of an annual subscription. It was further agreed that it should have a council, to represent all the various interests concerned, and an executive committee of twelve members. Five of these members were appointed from the meeting—namely, Sir Thomas Hooper, Dr Portescue Fox, Dr Kerr Pringle, Dr C. W. Buckley, and Mr W. A. Appleton, and power was given to them to co-opt seven additional members, as well as a president and a honorary secretary. Pending the appointment of the latter, Dr M. B. Ray, who has had secretarial direction of the movement hitherto, agreed to continue in office. It was also agreed to ask the executive committee to draw up a regular constitution for the association, to be approved by a general meeting of members, and to hold an annual conference at which papers would be read and discussions take place. It was proposed further to set up a number of committees, to deal with the question on its medical, research, industrial, and approved societies sides.

Letters sympathizing with the movement were read from a number of doctors and men well known in national health insurance administration.

Scotland.

Department of Health for Scotland Chief Medical Officer

As announced in this column last week the Secretary of State for Scotland has appointed John Parlone Kinloch, M.D., to be Chief Medical Officer in the Department of Health for Scotland, which on January 1st, 1929, will take over the powers and duties of the Scottish Board of Health. When the Secretary of State decided to ask Parliament to supersede the Scottish Board of Health by a Department he clearly contemplated the appointment of a chief medical officer of health who would be head of the medical staff, with powers and duties similar to the chief medical officer of the Ministry of Health. As was explained at the second reading, a voting board of six, with two medical members, was not satisfactory from any point of view. The new appointment will make the chief medical officer effective head of the medical staff in all its work, subject to proper adjustments between him, the Permanent Secretary, and the Minister. The Permanent Secretary was appointed some time ago. Sir John Gilmour has now taken the second essential step in establishing the new executive.

Dr Parlone Kinloch, who is a West of Scotland man, graduated in medicine at Glasgow University in 1909. In 1910 he took the D.P.H. of Cambridge with distinction, and in 1913 the M.D. of Glasgow with commendation. He has had a very wide range of clinical and administrative experience. After holding a succession of resident posts, he was resident medical officer, Ruchill Fever Hospital, Glasgow, for three years, then deputy medical officer of health for the city of Aberdeen and reader and lecturer in public health to the University of Aberdeen, and on the retirement of Professor Matthew Hay in 1923 he became

MOH to the City of Aberdeen and head of the public health department in the University. He is physician superintendent of the City Fever Hospital and of the Woodend Municipal Hospital. During the war he had a full term of military service with the R.A.M.C. All through his career Dr Kinloch showed great readiness to react on the new materials that came within his range, as is proved by a long series of contributions to technical medicine published in these columns and elsewhere. Moreover, apart from his annual reports, he has made a series of some twelve or more special reports on subjects such as fish meal factories, hospital buildings, municipal hospital services, and housing. In addition to these incidental investigations the output of Dr Kinloch's department has been striking. He has inspired a team of workers in the public health service to produce a remarkable series of contributions to practical problems affecting the health of the community. In particular, his last annual report contains work prepared under his stimulus on ultra violet radiation and the standardization of treatment with therapeutic lamps. His best achievement as an administrator has been the unification of the public health and Poor Law hospital services of Aberdeen by agreement with the authorities. Over a year ago the Secretary of State opened the new Municipal Hospital, and expressed admiration for the way in which the city of Aberdeen had carried through the amalgamation of the services of Poor Law and municipality. This change is entirely on the lines of the hospital developments contemplated in Scotland as the result of the new reforms in local government. Professor Matthew Hay, in his long period of fruitful administration in Aberdeen, prepared the way for many great changes. Dr Kinloch has taken full advantage of the larger lines of administration, and he has shown great originality in concentrating the full force of the official medical institutions on clinical work. This is the distinctively original note in his work. Incidentally he has demonstrated the possibilities of co-operation of the public health, Poor Law, school health, and Board of Control workers of the city, and of these authorities with the county authorities and with the general practitioners of the north-eastern region. Dr Kinloch is only 43. He comes to the work of the new department with highly specialized training for the problems now rapidly emerging in the reorganization of medical services. Under the new regime he will be able to direct the full strength of a large and capable staff to the best advantage in every section of public medical work.

Mental Defect in Scotland

Dr R. D. Clarkson, superintendent of the Royal Scottish National Institution, Larbert, addressed the City of Glasgow Society of Social Service on November 8th, on the problem of the feeble-minded. Mental deficiency, he said, was at the root of many social problems, and there was a great deal of popular prejudice on the subject. It was extremely difficult to define mental deficiency, and the definitions in the Mental Deficiency Act were not helpful. The highest grade defined in the Act was that of the feeble-minded, who required supervision and control for their own protection or the protection of others in the case of children the feeble-minded were those who were incapable of obtaining proper benefit from the ordinary instruction in elementary schools. It was generally agreed that about 1 per cent of all children in schools did not derive benefit from the teaching and on this basis there should be about 50,000 mental defectives in Scotland. The number known to the General Board of Control was, however, only about 3,000. This was too low a figure, but it was certain that incapacity at school did not necessarily mean incapacity to earn a living in later life. The definition in the English Act was that mental defectives were persons with arrested or incomplete development of mind arising before the age of eighteen from inherent causes or induced by disease or injury. This showed that no distinct line could be drawn between the mental defective and the normal member of the community, and it was probable that heredity did not account for a large proportion of defectives. There was far too little institutional accommodation for defectives in Scotland for of the 3,000

known to the General Board of Control, about 1,800 were in institutions, and of these only 634 were in institutions for adults. Experience at the Lambert Institution had shown that every training school for defectives should have an industrial colony in connexion with it under the same management, because defectives "transplanted" badly from one institution to another. The Council of Social Service could not do better work than to deepen interest in the immediate provision of further institutional accommodation.

Teeth and Health

In the course of a lecture on the teeth in relation to health given in Edinburgh on November 7th, Dr D. L. C. Radford, dental surgeon to the Royal Infirmary, said that dentistry stood on the threshold of preventive medicine, for if the functions of the teeth were not fulfilled many physiological processes might be interfered with. The bony of the face were easily moulded in early life, and bad habits resulted in permanent disfigurements. Thus thumb and lip sucking or the use of a "comforter" by infants left permanent effects in the pushing out of the upper teeth and in the backward deviation of the lower teeth, so that the facial contour was altered. Mouth breathing at a later stage, whether as a habit or due to adenoids, resulted in poor development of the upper jaw and crowding of the teeth, with resultant narrowing and pinching of the face, while the lungs were left less strong than they should be owing to the absence of warming of the air that should take place in the nose. Clean teeth, the lecturer stated, could not decay, and the wide prevalence of dental decay was due to ignorance and carelessness. Caries was regarded as a chemico-bacterial process caused by the activity of certain bacteria in the presence of certain food. In many diseases, further, dental disease was the primary or contributory cause. The tubercle bacillus in some cases undoubtedly passed through carious teeth to the glands in the neck. Various diseases of the chest, such as septic pneumonia and heart disease, were also traceable to a septic condition of the teeth, while other general diseases, such as anaemia, neuritis, neurasthenia, and joint affections, had important relations to the same causative process. The degree of oral cleanliness sometimes decided whether the end of a serious illness should be death or recovery. The preventive treatment of this serious state of affairs was simply the practice of cleanliness. How many persons, he asked, cleaned the mouth after every meal? Effective brushing of the teeth must be done intelligently, with a brush of such a size and shape that all parts of the teeth and gums could be reached, and its bristles should be sufficiently stiff to remove debris from between the teeth and to clear out the stagnation areas. The direction of the brushing movement should be from the gums towards the edges of the teeth, for the usually horizontal brushing was not sufficiently effective. Another point of great importance was the eating of fruit and raw vegetables such as apples. The common practice among some parents of giving children a soft biscuit, chocolate, or sticky sweet at bedtime was bad for the teeth, and was very likely to cause dental disease, with the resultant impairment of physical growth and development in the child, and indifferent health in the adult.

Central Midwives Board

At the recent examination of the Central Midwives Board for Scotland, held simultaneously in Edinburgh, Glasgow, Dundee, and Aberdeen, 119 candidates passed out of 133 who appeared for examination. The successful candidates were trained at the following centres: 20 at the Royal Maternity Hospital, Edinburgh, 46 at the Royal Maternity Hospital, Glasgow, 13 at the Maternity Department, Royal Infirmary, Dundee, 2 at the Maternity Hospital, Aberdeen, 12 at the Queen's Institute of District Nursing, 8 at the Elsie Inglis Memorial Hospital, 2 at the Edinburgh Lying-in Institution, 7 at Stobhill General Hospital, 2 at the County Maternity Hospital, Bellshill, 2 at the Eastern District Hospital, 3 at the Western District Hospital, Glasgow, 2 at the County and City of Perth Royal Infirmary.

Ireland.

Report of the Free State Public Health Department.

THE second report of the Irish Free State Department of Local Government and Public Health, which has now been issued, covers the period from April, 1925, to March, 1927. A description of the original constitution and functions of the department was given in a review of its first report, for the years 1922-25, which appeared in the *Journal* of March 12th, 1927 (p. 489). The present report consists, in addition to an introductory note and numerous appendices, of five main sections devoted to general administration, public health, housing, poor relief, and roads. Important changes in local government were made by the Local Government Act, 1925, which came into effect in October that year, and which involved the centralization of public health administration in each county outside the urban areas under one county authority, the abolition of rural district councils, and a reform of the law relating to the granting of superannuation allowances and gratuities to officers of local bodies. At the same time, with the object of securing a uniform system of administration, the principle of local adoption was withdrawn from a number of important public health statutes (including the requirement of notification of infectious disease and of tuberculosis), and their operation was extended generally throughout the Free State. The Act required also the appointment for each county of a whole-time county medical officer of health. Under the Local Authorities (Officers and Employees) Act, 1926, there was established a commission charged with the duty of recommending persons for various types of appointment under local authorities, including those in which the qualifications are wholly or in part professional or technical, and, as stated in the *Journal* of October 30th, 1926, county councils have been urged to appoint medical officers of health for their areas, and to adapt this procedure in making appointments. The Local Government Act, 1925, defined the duties of the Minister in relation to health, placing them upon a broader basis than before, and the report under review therefore deals with the work of the department in the initial stages of the fulfilment of its new responsibilities.

Decrease in the Death Rate

IN respect of general health conditions, the census of 1926 has furnished a reliable basis for the calculation of local death rates. The larger town districts in that year showed a death rate of 15.5 per 1,000 of the population from all causes, and of 1.5 from the principal epidemic diseases, among which diarrhoea and enteritis figured prominently as a result of a hot dry summer. In 1916 the death rate of the towns was 19.3 per 1,000, so that there has been a gratifying measure of progress in health generally, which is attributable to the collective result of a variety of causes. There is not, however, the report states, a single county in which to some degree restrictions of finance do not retard valuable improvements which would be effected by additional water supplies and sewerage schemes. Local bodies are showing more disposition to embark on public health works, but in some counties there is a tendency to withhold approval to such schemes unless the ratepayers in the area directly benefited agree to bear the cost, which in small towns is often impossible. As a result of this desire to confine liability within narrow limits an indefinite postponement of proposed works frequently follows. The country is subjected to a serious tax by reason of the insufficiency of its water and sewerage services. Enteric fever and diphtheria are unduly heavy in mortality and incidence, and impose avoidable sacrifices of life and expenditure in hospital and medical charges. Among infectious diseases, typhus fever remains rare in the urban districts, only one case being recorded in the years 1925-27, while in rural districts its incidence has decreased considerably also. The extensive outbreaks of enteric fever formerly experienced in the country areas are now unknown.

Maternity and Child Welfare

In connexion with maternity and child welfare the policy of the department has been to encourage and assist voluntary agencies and voluntary effort, and it has been instrumental in maintaining district nursing societies in many parts of the country. The nurses connected with these bodies, of which 105 exist outside Dublin, in addition to other duties, act as health visitors under the maternity and child welfare schemes. Trained nurses who are to undertake this duty are given a supplementary course of instruction. In the development of the public health service it is intended to utilize existing nursing services to the fullest extent. During the two years under review disbursements from the grant in aid for maternity and child welfare work amounted to £29,784, of which £12,993 was paid to local authorities, and £16,791 to voluntary agencies. In view of the reforms in the organization of the public health administration it was deemed inexpedient to press for the inauguration of school medical services in the counties, and little progress has been made in this direction. An account of the present position and of the system adopted in Dublin, recently given by General Mulcahy, Minister for Local Government and Public Health in the Free State, was published in our issue of November 3rd (p. 817).

Tuberculosis Schemes

Despite the application of compulsory notification of tuberculosis to all parts of the country, notification is not yet generally operative; but it is expected that with the appointment of county medical officers of health some improvement will take place in this respect. Comprehensive schemes for the prevention and treatment of tuberculosis, as mentioned in the last report, are in force in twenty-two counties and in the boroughs of Dublin and Waterford, while partial schemes, dealing with insured persons and their dependants only, exist in the counties of Meath and Wicklow. Some progress towards the adoption of comprehensive schemes has been made in the counties of Meath and Cork and in the boroughs of Cork and Limerick, but in three counties—Longford, Roscommon, and Wicklow—no action has yet been taken to provide the facilities available elsewhere. Each approved scheme is in charge of the medical superintendent of the central tuberculosis dispensary, which is generally situated at the administrative headquarters of the area. Twenty such dispensaries are in existence, but in several schemes proper facilities have not yet been provided. There are now 134 branch dispensaries. The approved institutions contain in all 2,100 beds specially reserved for tuberculous patients, the sanatoriums for early and moderately early cases of pulmonary tuberculosis comprise 851 beds, and for cases of surgical tuberculosis 495 beds have been specially provided. Patients treated under approved schemes numbered 11,104 in 1925-26 and 12,628 in 1926-27, compared with 7,132 in 1922-23. The death rate from tuberculosis was 1.57 per 1,000 of the population in 1925, and 1.47 in 1926.

Treatment of Venereal Diseases

Since 1925 schemes for the provision of treatment of venereal disease have been adopted in the borough of Cork and the counties of Offaly and Westmeath, these schemes being similar to those already in operation in Dublin and four counties. Normally the State grant is 75 per cent of the net expenditure. The arrangements generally provide for assistance to medical practitioners (by free pathological reports and, in certain cases, gratuitous supplies of salvarsan substitutes), treatment centres, and pathological laboratories. An inquiry by an interdepartmental committee as to the steps, if any, desirable to secure a diminution in the extent of venereal disease has been concluded, and its report is now under consideration.

Dispensary Medical Service

Coeexistent with the county and district hospital services in the Free State are the facilities afforded under the Medical Charities Acts for free medical attendance for the sick poor at their homes and at dispensaries. The number

of medical officers concerned in this on March 31st, 1927, was 634. In special cases consultants may be employed, while for confinements the services of the dispensary doctor and a qualified midwife are available. Medicines and medical and surgical appliances are supplied gratuitously to patients. New cases at the dispensaries numbered 458,387 in 1925-26, and patients attended at their homes 120,069, the figures for 1926-27 being 499,952 and 139,755 respectively. During the period under review the Local Government Act of 1925 conferred pension rights on medical officers, nurses, and midwives, and made continuous service pensionable irrespective of the area in which it is served. Improved scales of salaries for medical officers have been adopted in every county area except Longford, Mayo, and Wexford.

The Poor Law Hospital Services

In the Poor Law hospital services much progress has been made in improvements of the existing institutions, and in several areas extensive alterations have been carried out. New hospitals are being erected at Bantry and Kantuik. Galway Hospital is being developed on the lines of a large general hospital, with provision for operative and special forms of treatment, resident medical officers, and a visiting staff. Regulations have been issued governing the admission of paying patients to Poor Law hospitals. Satisfactory progress has been made in the development of the home and school established by the Sisters of Charity of St. Vincent de Paul for mentally defective children.

Progress in Housing

The results of the various Housing Acts in force during the years 1925-27 have been exceedingly gratifying, and the provision of new houses in rural areas is described as having surpassed all expectations. Many of these houses are situated in the most remote parts of the country and in the poorest districts of the west, the report states that "in many cases the most admirable determination, involving often personal privation and sacrifice, has been shown by persons of little or no means in the provision of healthy homes for their families." The result has been a substantial improvement in the standard of housing, which must in due course be reflected in health conditions.

General Progress

It will be seen that the main features in the development of the Free State's health services have been matters relating to organization and administration. The report gives evidence of the fact that the local authorities, in several cases, have been exceedingly slow to assume their full responsibilities, but at the same time shows the determination of the central power to secure improvement as financial considerations and considerations of practical policy permit. Due importance has been attached to the appointment of whole-time medical officers of health and to the improvement of conditions of medical officers in certain branches of the public service. The fruits of these reform measures, and of the others to which reference has been made, should be a gradual improvement in general health conditions, and, what is equally important, an increased recognition among local authorities and members of the public of the economic and social value of adequate public health services.

Insurance Medical Certification in the Free State

The National Health Insurance Commission recently addressed a circular letter to medical certifiers, which stated that from inquiries received, and from certain reports in the press, it appears that there is considerable misunderstanding and doubt as to the nature and extent of the proposed alteration in the scheme for the change of the pool area for certification. It may be added that the Commission departed from its usual custom, and did not forward a copy of the letter to the Irish Medical Committee. At the next meeting of this body it will be clearly shown that the figures used by Dr. Power, chairman of the committee, and by the Irish Medical Secretary of the British Medical Association, left no room for any misunderstanding with regard to the effect of the proposed change. It is difficult to

appreciate the urgency expressed by the Commission, which asks medical certifiers to state not later than November 20th whether or not they are willing to continue medical certification under the new conditions, as the agreements for medical certification, entered into in 1915, are still in existence, and the medical certifiers have expressed the desire that they should remain in force. The Commission does not claim that medical certification under their new scheme will be improved. The only argument that might appeal to a proportion of the medical certifiers is that under the new scheme their remuneration might be doubled or trebled. This aspect has been emphasized by the Commission to a far greater extent than the fact that this increase will mean a corresponding reduction in the remuneration of other medical certifiers.

England and Wales.

The London County Council and Slum Housing

UNDER the auspices of the Windsor Division of the British Medical Association, a public meeting was held at Maidenhead on October 19th to consider the problem of housing and health. The chair was taken by Dr J J Paterson, medical officer of health for Maidenhead, and Dr William Butler, senior medical officer to the London County Council, delivered an address on the subject of the provision of new houses since the war. He enumerated the essential elements of good housing, which included proper flooring and adequate lighting and ventilation, together with good sanitation. A point often overlooked was that the actual shell of a house accounted for only 25 per cent of the total cost, the expense of building was largely due to the provision of additional requirements. After many inquiries the London County Council had found that little could be done in the way of reducing the cost of building, and that the brick house was the most economical in view of its durability. The slum houses in London were most unsatisfactory because they were rapidly decaying, although they had good water and some fair conditions. The difficulty was to abolish uninhabitable houses and to rehouse the inmates. Since the war the London County Council had cleared away about 100 acres of slum houses in which the tenants had been living under bad conditions of lighting and ventilation, promoting the spread of tuberculosis and other diseases. Still more clearance work remained to be done, but the cost was very great. There was the additional problem of providing new houses on the old sites so that the inhabitants should not be displaced far from their work. Dr Butler described the operations of the Council on the new building estates at Dagenham and Becontree in Essex, where there would be accommodation for 120,000 people. It was proposed to provide small cottages as well as flats, the speaker detailed the minimum requirements for such houses, and added that the utmost economy had to be practised in their construction in order to keep down rents. Miss Joan Sunderland, house property manager for the Ecclesiastical Commissioners, described the old houses owned by the Commissioners, and remarked that if a house was not carefully built it aged very rapidly. The improvement of old cottages in the country was difficult and expensive. Many of them had been built after the Napoleonic wars, when there was great need of rehousing of returned soldiers; the basement house was perhaps the worst of the types then provided. Though there were many difficulties in the way of clearing the slums built at that time, there were certain advantages as regards privacy, garden space, and beauty attached to some of the buildings then erected. The average rent of old houses in South London was 3s a room and it was obvious that the same terms could not be available in the newer houses. Miss Sunderland thought that under the London County Council schemes there would be a tendency for the very rich and the very poor to remain in the centre of London, while those in intermediate circumstances moved further out. The chief essential in the problem of housing was management, because good supervision prevented degradation into slum living.

Physiology and National Efficiency

A public lecture on physiology and national efficiency was given at King's College, London, on November 14th by Professor R J S McDowall. The lecture is one of a series of nine on the indebtedness of industry to pure science, which is being given during the current term. Professor McDowall said that national efficiency depended on the efficiency of the individual, to be efficient a man should always be capable of doing his best in the minimum time and with the minimum waste of material. The lecturer explained that accurate reasoning was based entirely on experiments performed in physiological laboratories, in the first instance in the pursuit of pure science, and remarked that physiological investigations had led to the discovery of remedies for scurvy, rickets, diabetes, and many other ills. He recalled how Lord Lister, in his first lecture in the college, described the essentials of the souring of milk, and how eventually he demonstrated its fundamental importance in relation to aseptic surgery. In conclusion, Professor McDowall quoted instances to show that the more time a man spent at work the less work he might do. This fact was founded on simple physiological principles, the neglect of which resulted in a considerable loss of national efficiency.

Correspondence.

OPLN-AIR LITE AND MOTHERHOOD

SIR,—We are told that in spite of better midwifery and better trained nurses and doctors, we lose as many mothers in childbirth as we did thirty years ago, and that in 1927 some 2 690 women died in childbirth, and of these, 1 026 of puerperal fever—a preventable disease. I think that all deaths in childbirth should be preventable, not at the time of delivery perhaps, but by proper maternal hygiene, concerning itself with the growth and development of the mother.

I was in India twenty years, and was puzzled by the fact that when I spoke of the awful cases I saw of childbirth among Indian women in a zenana hospital, some lady always said, "But I thought Indian women had such an easy time, my brother in Assam says the coolie women just go behind a bush and have a baby and go on with their work." Or another would say, "I don't understand this, for my husband said that on such and such an expedition they had native women to carry their baggage, and one of them had a baby on the roadside and was none the worse, she just went on with the march, carrying the child in her arms." And yet here were hospitals frequented by the better class Indian women, where every maternity case had some difficulty or they would not have come in to see us.

I began to investigate the Caesareans—we had twenty-nine in one year, all with acute deformity, in many cases even precluding a craniotomy, most of them septic from having been in the hands of untrained midwives for several days. The poor women labouring in the fields or working hard on the great rice boats never came near us, they delivered themselves. Why this great difference? Closer acquaintance revealed the fact that all our worst midwifery cases were among richer people living in purdah—that is, more or less secluded indoors in rooms looking into high courtyards to ensure privacy. They went out very little, and were then usually veiled. I think this association of outdoor life and plenty of air and sunshine with easy childbirth and of indoor life in ill-ventilated rooms and darkness with difficult childbirth will be found to hold good not only in India and Kashmir, but all over the world.

Where is maternal mortality highest? In crowded towns and in colder climates (where people are inclined to lead a more indoor life), among city dwellers, factory workers, and also among the luxurious rich, overclothed townspeople and the delicate who are kept indoors on that account. Who have easy and safe labours? Country people, where the women and children are much out of doors, field workers, those who are in the open air from childhood (Where shall we find them now when all must sit indoors

behind glass windows at school while the sun shines outside?)

Recently the necessity of light on the skin for the production of vitamin D, the vitamin concerned in bone development, has been carefully studied. Without light the calcium and phosphorus needed for bone development leave the body in faeces and urine, and rickets or osteomalacia results according to the age of the patient when the deprivation of light takes place. Those in the open air develop a normal skeleton, and the pelvis is the size Nature intended it to be, those in darkness are under-developed. This may have escaped notice, because I cannot find any routine measurements of the circumference of the pelvis in school children at various ages anywhere in the world. Other observers have come to the conclusion that in every race the size of the head is related to that of the pelvis through which it is to be born, and that all births should be normal provided the mother has attained normal development.

A small fault in development would upset an otherwise perfect adaptation between head and pelvis. American observers have shown these failures in development can arise at any time after birth. The pelvis doubles in circumference from birth to 7 or 8 years old, and triples from birth till puberty at 14 or 15, thus early rickets can affect its normal development, perhaps so slightly as to escape notice until the confinement. Many children kept indoors, overclothed, only allowed out in deep perambulators covered with black mackintosh and a black hood, will be wanting in the bone development suitable to their age, and this loss can never be made up. Ask any woman with an abnormal pelvis as to her past history, and this factor, I think, can be traced. The association of difficult childbirth with the same areas where tuberculosis is prevalent points to the same cause. It seems of little use to blame doctors and midwives for ignorance and want of skill when the fault is not primarily theirs, but is due to a failure in skeletal development on the mother's part, beginning possibly in early infancy and rendering labour difficult or abnormal.

I do not, of course, suggest that all cases of difficult labour are caused by disproportion between head and pelvis, but many certainly are, and for this reason labour is difficult instead of being natural and easy. If normal, there is no need for intervention and no risk of sepsis. In case this idea—that the growth of the human skeleton depends on sunlight—seems far-fetched, I would briefly point out that the smallest races, the pygmies, live in dark forests, that the biggest races live on plains or plateaux, that Limonsin and Sardinia produce small people, but these, if removed as infants from their native valleys, develop into people of normal height, that all town dwellers are shorter than countrymen, especially clerks and factory workers, and their shortness is in the lower limbs, which, being nearer the ground, receive less light in streets, houses, and schools. It does not seem preposterous to suggest that difficult midwifery is caused by under-development of woman's pelvis, due to want of light in home, school, and factory.

The moral is that ante-natal hygiene must concern itself with the mother's own development from birth till maturity, when, if normal development has been allowed, there need be no fear of her life being lost in childbirth. A properly developed pelvis would do far more to diminish the risks of maternal death than assistance called in to avert danger when parturition is imminent.—I am, etc.,

London W. October 28th

SURGICAL TREATMENT OF GASTRIC AND DUODENAL ULCERATION

Sir,—In Mr. A. J. Walton's interesting article upon the results of surgical treatment in gastric and duodenal ulceration (November 3rd, p. 784), he refers to a recent paper in which the author "publishes a table giving 90 per cent of satisfactory results after partial gastrectomy, but his figures do not include those patients who died, 9.2 per cent." As this obviously refers to a paper of mine published in the *Lancet*, August 11th 1928, I feel that some explanation is necessary. The title of this paper was "The later results of partial gastrectomy," and although,

as Mr. Walton shows, the mortality figures were given, it was impossible to include these in an investigation into the late results of an operation. The rather high mortality was deplored, and suggestions were made as to how it might be diminished in the future.

In the evaluation of any operative procedure there are two main points to be considered by the surgeon, one the worth of the procedure as a cure, and the other the risk incurred in its performance. These are obviously interdependent, so that if it can be proved of two operations that one gives a much larger percentage of permanent cures than the other there is justification for extra risk in its performance. For this reason the high percentage of satisfactory results—namely, 95—was held, in the above article, to be some justification for the mortality.

I notice that Mr. Walton uses an argument against partial gastrectomy only too common at the present time. "The removal of three-quarters or more of the viscus for an ulcer, often only 1 cm. in diameter, seems an unnecessarily severe and deforming operation." But surely he does not believe that the ulcer is the whole of the disease, and if not, then the size of the ulcer, whether large or small, is of little importance. It would almost be as logical to state that the removal of the whole breast, muscles, and axillary tissues for a carcinoma the size of a small nut appears an unnecessarily severe procedure, as indeed it was considered in earlier days.

Mr. Walton has himself proved (at the International Cancer Conference) that a considerable percentage of cases of carcinoma of the stomach start as simple ulcers, that a lesser operation than partial gastrectomy will prevent this metamorphosis has yet to be demonstrated, on the other hand, that carcinoma may follow gastro-enterostomy performed for perfectly simple ulceration is certain—I am, etc.,

London W.1, Nov 10th

NORMAN C. LAKE

OBSERVATION OF THE CIRCULATION IN THE MOUSE LIVER

Sir—In the *British Medical Journal* of April 8th, 1921 (p. 526), I communicated the fact that I had been able to observe the circulation in the glomeruli of the frog's kidney, and measure the pressure in the capillaries of the glomeruli.* Dr. James McQueen, extending this line of observation, reported in the *British Medical Journal* of December 17th, 1927 (p. 1137), that he had been able to observe the circulation in the edge of the liver of small toads. A pulse might be seen in the hepatic venules, due to each systole of the auricle momentarily stopping the flow. McQueen observed that many of the capillaries appear naturally to show stasis. I was able to confirm this observation and to measure the pressure in the capillaries of the toad's liver†. The inflow was stopped by a pressure of 2 to 3 mm. of mercury. A compression a little greater than this in amount sufficed to squeeze the blood out of the capillaries of the liver, showing how the respiratory rise of abdominal pressure must further the hepatic circulation. Later McQueen observed the capillaries in the edge of the liver of dead mice, and asked me to make observations on the living anaesthetized animal, he then having no licence to do so. Dr. McQueen has now obtained a licence, and confirms the substance of this note by his own observation. I have made these observations, and find it possible to get a surprisingly beautiful view of the circulation in the thin edge of the mouse liver. I used small, half-grown mice, fasted for twelve hours or so, and then anaesthetized with urethane. I make a cut through the skin and abdominal wall on the right side of the front of the abdomen, put the animal belly upwards, half on its side and manipulate the exposed lobe of the liver so that its edge comes to be over the transparent membrane (areolar tissue of rabbit) which covers the Roy-Graham-Brown apparatus, which I use for measuring capillary pressure. The liver clings to this membrane, and by gentle traction on the animal the edge of the lobe becomes sufficiently thin to be transparent to illumination from a small

For further information on this subject see Hill and McQueen *Brit. Journ. Exper. Path.* 1928 9 p. 127.
† See *Brit. Journ. Exper. Path.* 1928 9 p. 145.

are reflected by the mirror under the microscope. A half-inch objective suffices to show up the portal venules, hepatic venules, and network of capillaries joining the two, and the blood is seen scurrying along in continuous stream, with no sign of stasis or of pulse in successful preparations. In less successfully made preparations, as respiration becomes feeble stasis appears, and as the state of shock increases becomes general.

A pressure of 2 to 3 mm. of mercury suffices to stop the flow from the portal venules, and even to reverse this flow and blanch the edge of the lobe, this is compressed between the membrane of the apparatus and a glass cover which is brought gently down upon the edge of the liver so as barely to touch it. A drop of Ringer's solution ensures that the compression is equally applied. The membrane closes a chamber with glass floor for transmitting light, the chamber is in connexion with a manometer and a tubing for producing compression. The edge of the liver pulsates with each respiration, and this is taken as a sign of freedom from compression, as should be the case when the pressure in the apparatus stands at zero. The low pressure which suffices to maintain the flow in the capillaries is balanced by the tissue pressure of the liver, the whole being enclosed in the capsule of the liver. There is then no adequate pressure for producing a filtration of lymph in the liver, as has been assumed. As in other organs, both secretion and flow of lymph are governed by the action of the living liver cells.—I am, etc.,

MODERN PROBLEMS IN NEUROLOGY

SIR,—It is an old and rather discredited method in criticism to assign views to an author which he does not hold or in so many words state, and then to proceed to demolish them. The writer of your leading article reviewing a recent book of mine has none the less resorted to this particular technique.

I do not attribute the escape of emotional reflexes "exclusively" to lesions involving cortico-pontine and cortico-bulbar paths. I do not ascribe various Parkinsonian symptoms mentioned by your reviewer solely to rigidity. In each of these instances (and, indeed, in still another) my views have been misrepresented more or less seriously, as might easily be shown by citation.

I am also criticized for under-estimating the importance of the constitutional factor in epilepsy. As I was not concerned with etiology, and mention it only incidentally, this is mere para-criticism, to which there is no end.—I am, etc.,

London W 1 Nov. 10th.

S A KILNER WILSON

HYPOCHONDRIA

SIR,—Dr Crichton-Miller's letter (November 10th, p. 866) on this topic has raised several points on which he professes disagreement with the views propounded by me at the discussion at the Royal Society of Medicine. I do not know on what ground he can base his criticisms, since he cannot have read more than the relatively brief summary given in your columns, and since so far as I know, he was not present at the discussion. If he was present he did not air his contribution then.

Most writers on hypochondria refer not only to an arterio-sclerotic factor in many cases, but to a variety of other predisposing conditions of an organic nature. Vagotonia, however, I did not mention, some personal inquiries made some years ago into that topic taught me that vagotonia is a doubtful concept to play with.

I am glad that Dr Crichton-Miller is, even unwittingly, in agreement with me on what I emphasized in the discussion—namely, the absence of anxiety in the clinical sense in the true hypochondriac. I also mentioned the probable etiological role of excessive egocentricity in some cases at least. It is a source of regret to me that in my endeavour to clarify the distinction between hypochondria and hysteria I should appear to Dr Crichton-Miller merely to obfuscate the issue. But these and a number of other points he will find described, in more detail than

was possible at the discussion, in a paper now in the press for the forthcoming number of the *Clinical Hospital Reports*, of which I propose to give myself the pleasure of sending him a copy, if he will be kind enough to accept it.—I am, etc.,

London W 1 Nov. 10th.

R D CILLESPIE

PRIVATE PRACTICE

SIR,—In the *Supplement* to your issue of November 3rd is published the draft report of the Private Practice Committee which was constituted by the Council of the British Medical Association after an enthusiastic resolution passed by the Representative Body to inquire into the encroachments on private practice now so prevalent, and to suggest remedies for that state of affairs. Every Division should study it most carefully and also read the very admirable report by Dr Cox on his visits to different areas of the country to collect pertinent information. The Committee suggests various recommendations to deal with the question. All members of the Association should study these carefully before deciding to accept or reject them.

There will be plenty of opportunity for debate on the revised report when it comes before the Council, the Divisions, and the Representative Meeting, so I shall only now draw attention to one of the recommendations which suggests as a solution of most of the difficulties a system of insurance. This is, in my opinion, a decent camouflage for a policy of extending the Insurance Act to all or many of the dependants of insured persons, and therefore deserves very careful consideration. Were this ever adopted it would indeed cut the Gordian knot, as, for all except a very few millions of the better off and upper classes, it would do away with private practice altogether. Such a state of affairs would be in direct conflict with the declared opinion and policy of the Association, which is that the best form of practice is that carried on between doctor and patient, subject only to the common law of the land and the ethics of the profession, and that contract practice should only be tolerated in such conditions that ordinary private practice is impossible.

If such an extension of insurance services were ever set up in such circumstances the work of the insurance practitioner would be increased far beyond what might be expected for women and young children in every class of the community require more attendance than the mere male, and a very great deal more of that work would entail home visiting. A dispeptic workman can walk to the consulting room. It would not be right to expect a young child with early measles or incipient bronchitis to wait its turn in the surgery. Also, I am not an expert on remuneration for such services, but I will take the dictum of one who is, and who stated in the Council, when the question of the inclusion of dependants was considered some years ago, that the practitioner could not expect to get the same capitation fee for dependants as that paid at that time under the Insurance Act, but that he would be lucky to get three-quarters of it, or it might be even less.

The whole financial question looms large. How would the enormous sum of money required be raised? (1) By contributions from employer, workman, and State, as in the panel system. (2) By the employer only. (3) By the workman only. (4) By the State. There are tremendous objections to each of these methods which in mercy to your space I will not particularize at present, but every practitioner should decide for himself and make his voice heard, whether he wishes to continue, even if only in part, a "private practitioner," or become one of a unit in a system of contract work, regulated, inspected, and limited, which will extend a most definite invitation to any Government, in the interests of economy and ease of administration, to set up a whole-time State salaried service, which I myself as a looker-on who has seen most of the game all over the kingdom during the last ten years, consider would be exceedingly bad, both for the health of the community, for the well being of what is still a learned profession, and the science and art of medicine and surgery.—I am, etc.,

London W 1 Nov. 9th.

G B TURNER

PAEDIATRICS OR PEDIATRICS

SIR,—I should like to support my friend Dr Still in his protest against the spelling "pediatrics." As you have the choice, please, await not the decision of the Society for Pure English, but let us have it in our *Journal* in the old English form, "paediatrics," and not in the new American, "pediatrics."

I like not the representation of "ae" and "oe" by "e," and other petty tricks of spelling. A gynaecologist is in America a gynecologist. In my book on *Caesarean Section* I have shown that eminent American obstetricians spell it *Cesarean*, and then proceed to enlighten their readers by giving the derivation from *cedo, cedere*. Shado of Phny, what next?—I am, etc,

London W Nov 8th

HERBERT R SPENCER

FUNCTION AND POSTURE

SIR,—I can fully endorse all that has been written about the importance of Mr F Matthias Alexander's contribution to medical science and the need for an impartial examination of his work, especially now that it is supported by the results of the physiological experiments of the late Professor Magnus. It is a gratification to those who have known how closely Alexander has kept his work to the strictly scientific principles he has laid down in his books to find that the report in your columns of Professor Wm Colin Mackenzie's researches on muscle function and development, together with your own acceptance of the principle of the relationship of posture to function, has opened the pages of a medical journal to a discussion of Alexander's work.

My object in writing, however, is to point out that Alexander has gone much further than Mackenzie, in that he insists upon the impossibility of separating functioning from the general use of the mechanisms, this general use being responsible for the erect posture as well as for every other. Indeed, I would go so far as to say that it is only when we understand and accept Alexander's position about "use" that the full significance becomes apparent of the connexion Mackenzie makes between functioning and posture. According also to Magnus, posture implies active functioning, but that is not all that Alexander means by "use," and it is because of the importance he attaches to the manner of the general use of the mechanisms that Alexander's work differs from any other that I know.

Mackenzie says, "We may define health as a correlation of all the bodily systems to the erect posture, and ill health as a failure of one or more systems to correlate to it," and he concludes by saying, "We are intent on surgical wards, theatres, and equipment, but an essential in any public hospital is a great department of myology wherein a scientific examination can be made for muscular defects, and their importance assessed." I may be wrong in assuming that by "muscular defects" Professor Mackenzie means those defects which arise from developmental causes, from paralysis or injury, or from a failure of some of the essential functions of the muscle cells. If so, these causes might in certain groups of muscles bring about want of correlation of the bodily system to the erect posture, but they would not account for those troubles which fill our consulting rooms and our hospitals with patients who are suffering from chronic diseases of every organ of the body and who (with no specific "muscular defects") still show a bodily system out of correlation with the erect posture.

Alexander's approach, however, throws light upon this problem. For, according to him, wrong use of the mechanisms, such as, for instance, the prevalent backward set of the head and the curve of the spine with the consequent shortening of stature, alters the conditions of the torso in such a way as to interfere with the satisfactory functioning of every organ and member of the body, resulting in ill health and chronic disease both of body and mind. He claims that unsatisfactory general use of the mechanisms of the body (with its consequent adverse effect upon posture) is always associated with disease, and that, as long as this general use remains unsatisfactory, defects in posture, with the associated unsatisfactory functioning and disease, must continue, despite every effort we may make to cure them, so that human beings by their unsatisfactory use of themselves, not only in the erect posture, as in standing and

walking about, but in every other, may be said to be slowly but surely inducing in themselves those conditions which we always find associated with functional disorders and disease.

With the appliances of clinical medicine and physiological science that we have at our command, it is surely possible to establish the truth or otherwise of Alexander's claim. It is for clinical physiology to test whether in a given case any improvement in the conditions of posture and vital functioning has taken place as the result of an improvement that has been brought about in the manner of the general use of the mechanisms.—I am, etc,

Bexhill, Nov 8th.

A MURDOCH, M B, C M

INJECTION TREATMENT OF VARICOCELE

SIR,—In his paper on injection treatment of varicose veins, read before the Sussex Medico-Chirurgical Society, as reported in the *British Medical Journal* of November 10th (p 848), Mr Delisle Gray suggested that varicocele also might be amenable to treatment by injection. Some varicoceles are. Within the last few months I have so treated seven cases.

The patient stands with buttocks against the side of the examination couch, and his cleansed scrotum is grasped and manipulated by the fingers and palm of the operator's hand so that turgid loops of varicocele are pressed firmly against the lower anterior scrotal wall and their outline is made clearly protruding and visible. Then, without relaxing this grip, the operator carefully passes the sharp needle of the syringe containing the injection fluid through the scrotal wall into the lumen of what appears to be the most protruding loop of vein. With unengaged finger, or fingers, of the syringe hand the piston can be sufficiently withdrawn to suck blood into the syringe, thus making certain that the needle is really in a vein. The scrotum is then released gently and steadily, to ensure that the needle remains in the vein, and the injection given. The needle is now withdrawn, while the operator's free fingers and thumb pinch the varicocele and scrotum at the point injected, and, while the varicocele is so held, the patient is told to lie on his back on the couch. The pressure is then released, and the scrotum and contents lifted up towards the pubes, and kept so raised for ten minutes.

No haematoma of the scrotum has followed this technique. The puncture point in the scrotum is sealed with collodion and the patient allowed to go about his business. Twenty-four hours later the varicocele can be felt as a soft, solid, and tender structure. After seven days the veins are hard and still tender. During this time the patient has suffered more or less dull, dragging pain in the scrotum and in the inguinal canal, the cord on palpation being slightly thickened and tender. No inflammation of the scrotum itself has been noticed. Four of these seven cases examined over three months after injection were apparently completely cured, the veins of the former varicocele being still palpable as very thin, hard, wiry cords, and the testicle apparently unaltered. About the other three cases it is too early to predict, as only two to three weeks have elapsed since they were injected.

In each case one injection only of 1 c cm of a solution of quinine hydrochlor 4 grams, urethane 2 grams, aq dest 30 c cm was given. They were all "large" varicoceles—large enough to make the operation comparatively easy. Quite recently I have attempted, but without success, to treat a decidedly smaller varicocele. On three separate occasions my needle point failed to enter any one of the varicocele loops. In the end this patient was told to wait till his varicocele became large enough to be injected.

Tinct iodi on the scrotum masks the outline of the varicocele loops: it should therefore be washed off with methylated spirit. This alcoholic cleansing admittedly causes contraction of the dartos, and, what is worse, of the varicocele, yet plainly, the scrotum calls for even more careful

the leg with varicose veins. How large the varicocele must be for successful injection appears to be conditioned mainly by the operator's skill. Hot weather or a hot bath, and a patient able to grasp his own scrotum properly, make the operation easier. So does a skilled assistant.—I am, etc,

London, W 1 Nov 8th.

H M HANSCHELL

HEART SOUNDS

SIR,—May I draw attention to the extraordinary statement in the *Epitome* of October 27th (p 55) headed "Common cardiac problems" that "recurring unduly loud first sounds produced by auricular reinforcement and auricular systolic sounds in the long pauses are of diagnostic value in heart-block." What authority is there for the suggestion that the thin-walled auricle is capable of producing any sound at all? I have pointed out repeatedly that a muscled when it contracts produces no sound whatever, and to suggest that the thin-walled auricle is capable of doing so is absurd. The number of vibrations per second of the muscled fibres is much below that required to produce an audible note. How "auricular reinforcement" whatever that may mean, can produce a sound is beyond my comprehension, and readers are entitled to know what is meant by such a phrase. We are told in this extract that these sounds are of diagnostic value in heart-block, but one is forced to think very poorly of diagnosis dependent on such questionable theory.

I have pointed out on several occasions that if the valves have anything to do with the production of heart sounds, it is extraordinary that when they are destroyed by disease and cannot possibly "flap" the first sound is magnified into a murmur. To say that the whirling of the blood in the heart is partly responsible for some of the heart sounds is incorrect, because everybody knows that a rubber ball full of water cannot possibly produce a sound when shaken. A ball only half full of water can, when shaken, produce quite a loud sound, because of the free surface of water in contact with air. There is no such free surface of the blood in the heart. The only freely moving fluid with a surface tension varying between systole and diastole is the pericardial fluid. I maintain that the normal heart sounds are produced by the movements of this fluid. If the pericardium be filled with an effusion the movements of the fluid are so restricted that no sound is heard, whilst were the sounds produced by the muscles or valves of the heart they would be heard all the more plainly, because fluid is such an excellent conductor of sounds.—I am, etc.,

DEFINITION OF DRUNKENNESS

SIR,—As police surgeon I frequently have to certify drivers of motor cars as "drunk." Before the magistrates I am always asked if I consider the prisoner to have been "drunk." I reply by asking what is meant by "drunk." No one has been able to tell me in court what "drunk" means. I then refer them to recent definitions of the word given by two judges and also by the British Medical Association. These definitions are roughly the same—that a man should be declared drunk if, as the result of alcohol, he is unable to do with safety that which he is attempting to do at the moment of his arrest. If, therefore, a medical man considers that as the result of alcohol a man is unfit to drive a car, this man, having been arrested in attempting to do this, can be declared drunk according to the above definition. This satisfies the court.

I have always found that accidents occur most frequently with those who, while taking alcohol, have abstained from food, and I always stress this fact in court.—I am, etc.,

TETANY INVOLVING THE RECTUS ABDOMINIS

SIR,—Dr Lerner in his memorandum published on September 15th (p 489) says that he can find no mention of a similar case in the literature. I would suggest that the contraction of the upper part of the rectus abdominis was in the nature of a simple spasm or cramp produced by coughing or stooping. I can supply three cases of a similar nature the first myself, the second my father-in-law, the late Kaid Sir Harry Maclean of Morocco, and the third a woman patient. I have had attacks for twenty-five years. They come on when I am stooping, and sometimes when coughing or sneezing. A very hard and very painful lump

misses in the top part of the rectus abdominis, in the left side. The remedy is to stand upright, lean back as far as possible, take a deep breath and hold it, and heavily press on the lump with both hands. My father-in-law had been bothered with similar attacks for some years, and many and varied were the diagnoses. One day he mentioned it to me, and was interested to find a fellow sufferer. Some months afterwards he had had a long day in the saddle and, entering the house, stooped down, and an attack occurred. I was there and looked at the lump, and the simple remedy suggested above was effective. The case of the woman was exactly similar, her attacks occurred when stooping at gardening, and the remedy was the same. In all three cases, before the cause and cure were explained the attacks were severe and relatively frequent. As soon as these were discovered the attacks declined in severity and number. Apprehension used to prolong the attacks. In all three cases the lump was in the upper part of the left rectus abdominis.—I am, etc.,

THE JEWISH PATIENT

SIR,—I venture to suggest that Dr Robert Hutchison's views on the Jewish patient, as exemplified at the Royal Society of Medicine on October 23rd and elsewhere, are a trifle obsessional. It is a mistake to draw conclusions as to the Jewish mentality in illness from experience among Jews around the London Hospital. My practice among Jews and Gentiles leads me to state that it is all a question of environment. Foreign Jews view their symptoms of illness with Continental excitement and demonstration, English Jews and English Gentiles contemplate the same symptoms in themselves with English calmness and control. It is not a matter of being Jewish or otherwise, but rather of being of English or of foreign upbringing.—I am, etc.,

A GIRLS' SCHOOL FOR ORPHANS OF DOCTORS?

SIR,—It seems to me that the time has arrived to make an effort to found a school for girls, the orphans of medical men and women on the lines of the great work done by Epsom College for boys.

On the back page of the *Times* on most days are printed advertisements of country mansions and lands to be obtained at a very reasonable price, sufficient to house twenty or more girls as a beginning. Could not the Medical Women's Federation and the Royal Medical Benevolent Fund Guild take this matter up and start say, a St Christopher's College for Girls, which could grow in the same way as Epsom College has grown? "Great oaks from little acorns grow." I am willing to give a small annual subscription as I do to Epsom College, and I believe that many others would also.—I am, etc.,

JOHN W BONE

Obituary

SIR NESTOR TIRARD, M.D., F.R.C.P.,

Emeritus Professor of Medicine, King's College, and Consulting Physician to King's College Hospital, London

WE regret to announce the sudden death on November 16th, at the age of 75, of Sir Nestor Tirard, consulting physician to King's College Hospital, whose name was well known to the medical profession generally through his work in the revision of the *British Pharmacopoeia*.

Nestor Isidor Charles Tirard was born on September 23rd, 1853. He came of French stock on his father's side, and part of his childhood was spent in France. From King's College School, then in the Strand, he went to study medicine at King's College Hospital, and had a distinguished student career, winning a scholarship and gold medal in forensic medicine and obstetrics, and a gold medal in physiology. He graduated M.B. Lond. in 1877, with honours in medicine, and proceeded M.D. in 1881. He obtained the diploma of M.R.C.P. Lond. in 1880, and was elected a Fellow of the Royal College of Physicians in 1886. From that time onwards he acted for many years as one of the examiners for the College, and served on the Council from 1908 to 1910.

At an early stage in his career Tirard began to interest himself especially in pharmacology and therapeutics, and he also carried out at King's College some useful researches in the pathology of renal disease. His published works included three books: *Diphtheria and Antitoxin* (which appeared in 1897), *Albuminuria and Bright's Disease* (1899), and a *Textbook of Medical Treatment* (1900), as well as contributions on nephritis and uraemia to the *Encyclopaedia of Medicine*. He was also for some years editor of the *King's College Hospital Reports*. In 1914 he delivered the Bradshaw Lecture before the Royal College of Physicians on "Clinical contributions to the study of glycosuria." His abiding interest in general clinical medicine was made evident to a succession of students during the many years he served as physician to King's College Hospital, and as professor of the principles and practice of medicine at King's College. Other appointments held by him included those of physician for twenty-six years to the Evelina Hospital for Sick Children, consulting physician to the Church Missionary Society, and physician to St. Luke's Hostel.

From 1895 to 1915 Tirard acted as secretary to the Pharmacopoeia Committee of the General Medical Council, and was intimately associated with the preparation of the 1898 and 1914 editions of the *British Pharmacopoeia*. In 1910 he was one of the delegates appointed by the British Government to take part in the international conference, held in Paris, on the unification of methods of analysis of alimentary substances. On several occasions the General Medical Council placed on record its appreciation of his skilful and assiduous work in connexion with successive revisions of the *British Pharmacopoeia*, of which he became senior editor in 1914, with Professor H. G. Greenish as junior editor on the pharmaceutical side. Largely, no doubt in recognition of these services, he was appointed in 1922 a Crown nominee on the Council for five years. After his retirement from the secretaryship of the Pharmacopoeia Committee he continued his services as honorary secretary. He became also a member of the Advisory Committee set up by the Minister of Health, the Secretary for Scotland and the Minister of Home Affairs for Northern Ireland, under the Therapeutic Substances Act of 1925, and was one of the British delegates at the International Pharmacopoeia Conference at Brussels in 1925.

Soon after the outbreak of war in August, 1914, he was placed in command of the Fourth London General Hospital with the rank of lieutenant-colonel R.A.M.C. (T), and threw himself into the administrative duties of commandant with characteristic zeal. He received the honour of knighthood in 1916, and in 1920 the Order of St. Sava was conferred upon him by the King of Yugo-Slavia.

Sir Nestor Tirard was for many years a member of the British Medical Association. He was vice president of the Section of Pharmacology and Therapeutics at the Annual Meeting at Edinburgh in 1898, and president of the same

Section four years later when the Association last met at Manchester. He was an active and valued member of the old Therapeutics Committee of the Association, serving as its honorary secretary from 1894 until 1902, when he was appointed chairman.

A memorial service, attended by many old friends and colleagues, was held on November 14th at All Saints', Margaret Street.

THE LATE DR J. J. PERKINS

Captain S. L. BHATTIA, I.M.S., M.D., M.R.C.P., Dean of the Grant Medical College, Bombay, writes:

As an old student of St. Thomas's Hospital, and one who came early under the influence of the late Dr J. J. Perkins, I may be allowed to add my humble tribute to his memory. It was in 1913 that I first came in contact with him in the class on systematic lectures in medicine at St. Thomas's. His lectures were most attractive and inspiring, each utterance bore a personal touch, which was at once captivating. His manner by the bedside made a deep impression on the minds of those around him. His infinite patience, practical wisdom, quick and thorough mind, and a talent for illustrating his remarks with humorous anecdotes made him one of the most popular teachers in the hospital in my day. He had a knack of quickly grasping essentials from a mass of clinical evidence, and his diagnosis was as accurate as it was brilliant. He took personal interest in his pupils, and was ever sympathetic and helpful, and, as one who is indebted to him for many kindnesses, I know that he felt deep and genuine delight in watching the progress of his old students. He was a great admirer of Sir William Osler, and, like him, was well versed in the classics and the humanities. The impression he has left behind on those who knew him is of one possessed of infinite sympathy for all, especially the young, and of stores of wisdom and knowledge held in a modest reserve. He was in every respect an ideal physician, and the influence of his personality and teachings is bound to be reflected in the life and work of his numerous pupils scattered in all parts of the world.

The following well-known medical men have recently died: Dr. GEORGE ROSOLIMO, director of the clinic for nervous diseases at Moscow, who has given his name to a finger reflex; Dr. CHAPOIS, director of the medical school at Besançon, aged 87; Dr. LUCIUS DUNCAN BULELEY, an eminent New York dermatologist, author of a work on syphilis in the innocent, which was awarded the Alvarenga prize in 1891 by the College of Physicians of Philadelphia; Dr. FLORENT JANSSENS, doyen of the medical profession at Louvain; Dr. XAVIER ARNOZAN, director of the *Journal de médecine de Bordeaux*, successively professor of therapeutics and clinical medicine in the Bordeaux faculty of medicine, associate member of the Académie de Médecine, author of a manual of therapeutics and a treatise on hydrology, and officer of the Legion of Honour, aged 76; Dr. WALTER BOOTH ADAMS, emeritus professor of pharmacology, therapeutics, and dermatology at the American University at Beirut, Syria, aged 64; and Dr. A. G. LUTKÉVITCH, professor of ophthalmology at Voronezh, South Russia, aged 65.

Universities and Colleges.

UNIVERSITY OF CAMBRIDGE

At a congregation held on November 9th the Vice-Chancellor (the Rev. Dr. T. C. Fitzpatrick) presiding, it was resolved to accept with gratitude the offer of the International Education Board of the Rockefeller Foundation to contribute £700,000 towards the cost of erecting the new University Library and to provide for much needed developments in the physical and biological studies of the University (see *British Medical Journal*, October 13th, p. 680).

The following medical degrees were conferred:

M.B. B.CHIR.—H. H. Stewart W. P. Parvis D. J. MacLennan
M.B.—The Hon. W. S. MacLennan

UNIVERSITY OF LONDON

The following have been recognised as teachers in the subjects indicated:

St. Bartholomew's Hospital Medical College: Dr. Geoffrey A. Harrison (chemical pathology); Dr. Rupert S. Scott (ophthalmology); London School of Medicine for Women: Miss Mariel Bond (physiology).

A grant of £130 from the Thomas Smythe Hughes Medical Research Fund has been made to Kathleen Cheevers M.B., to

be expended wholly on special apparatus and partly on special assistance for the purpose of investigations on the etiology and treatment of disseminated sclerosis.

Mr W G Spencer M S E R C S, has been appointed a member of the Board to Promote the Extension of University Teaching. The Senate has appointed Sir Maurice Craig, C B L, a governor of the Hospital Trust, Bedford.

Prosecutors' certificates have been awarded to John R B McBride (St Bartholomew's Hospital), Peter B Ashcroft (Middlesex Hospital) and Lennox W Willway (King's College Hospital).

Arrangements have been made with the Horton Mental Hospital for the instruction of students of the school in clinical psychiatry. Dr J R B Lord has been appointed honorary lecturer in clinical psychiatry.

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL.

The dates of the three lectures in the history of medicine to be given by Dr Charles Singer have been revised. On November 19th the lecture will deal with small pox, on November 26th with plague and on December 3rd with diphtheria. The lectures which begin at 4.15 p.m. will be illustrated by lantern slides and are open to all medical students of the University of London.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

An ordinary Council meeting was held on November 8th, when the President, Sir Berkeley Moynihan Bt, was in the chair.

The Diploma of Fellowship was granted to Roland Hodgson Beggan who has now complied with the regulations.

Diplomas of Membership were granted to 157 candidates, whose names were included in the list receiving the licence of the Royal College of Physicians printed in our issue of November 3rd (p. 826).

The President reported that Richard Anderson Hickling M B Ch Camb, M R C S, M R C P, of Westminster Hospital, had been appointed the fourth Stratfield scholar, the subject of his research being 'An investigation of the living cells of the blood and of the fusion into serous cavities by means of Sablin's survival staining technique in clinical cases.'

The President reported that Mr Warren Low's term of office on the Court of Examiners would expire in December. The vacancy will be filled at the next meeting of the Council. Applications should be sent in before November 28th.

UNIVERSITY OF GLASGOW

The degree of M.D. was conferred upon James Baird on November 10th.

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

A QUARTERLY meeting of the College was held on November 6th, when the President, Dr Robert A. Fleming, was in the chair.

Dr W T Benson and Dr R H H Newton were introduced and took their seats as Fellows. Dr J D Stuart Cameron and Dr A N S Cairnichael were elected Fellows.

The Hill Pattison Struthers Bursary in Anatomy and Physiology was awarded to Wai Ming Tso and the Hill Pattison Struthers Bursary in Clinical Medicine to Alan Mackenzie Fraser.

ROYAL COLLEGE OF PHYSICIANS OF IRELAND

At the monthly meeting of the President and Fellows, held on November 2nd the following admissions took place:—Fellow Timothy Maurice Healy. Members and Licentiates of the College J G Cullinane, L T Freeman, R T Jackson, V O McCormick, R A Q O'Meara, Eva H Tuug.

Captain F J O'Meara, R A M C, was elected a Fellow of the College on St Luke's Day, 1928.

The Services.

DEATHS IN THE SERVICES

Lieut Colonel Charles Thomas Blackwell, R A M C (ret.), died at Monaco on October 6th, aged 67. He was born in London on May 31st, 1861, and, after taking the Edinburgh double qualification in 1884, entered the army as surgeon on May 30th 1885. He subsequently graduated as M.D. Durh. in 1903, and took the D.P.H. of the London Colleges in 1904. He attained the rank of lieutenant colonel after twenty years service and retired on December 26th, 1917. He served in the Burmese campaign in 1888-89, receiving the Indian frontier medal with two clasps, in the North West Frontier campaign of 1897-98, with the Tichu Field Force receiving the medal with a clasp, and in the South African war in 1902, taking part in the operations in the Transvaal, the Orange River Colony, and Cape Colony, and receiving the Queen's medal with four clasps, and also in the recent great war.

Surgeon Captain Henry Arthur Kellogg Knight, R N (ret.), died in London on October 5th. He was educated at Bart's, and, after taking the M.R.C.S. and L.R.C.P. Lond. in 1903, entered the navy, attained the rank of surgeon commander on June 1st, 1917 and retired with an honorary step as surgeon captain on October 18th, 1926. He qualified as interpreter in French in 1905, and in German in 1910. During the late war he served throughout, and received the medals.

Medical Notes in Parliament

[FROM OUR PARLIAMENTARY CORRESPONDENT]

THE House of Commons ended the Debate on the Address on November 14th. Its other business during the week was to advance the Unemployment Insurance Bill and the Expiring Laws Continuance Bill. The text of Mr Chamberlain's Local Government Bill, comprising 115 clauses and twelve schedules, has been published. The Government hopes to secure the second reading of this bill and to make progress with the Committee stage before Christmas. As now issued the bill offers local authorities stronger financial guarantees than were contained in the previous draft. It also provides that in rural areas the administration of poor relief shall be delegated from the county authorities to local guardians committees, who may also be entrusted with the management of Poor Law institutions. Part II of the bill is concerned with the registration of births, marriages, and deaths. It reproduces the provisions of the bill formerly sponsored by Dr Fremantle, which Captain Gunston last session got through the House of Commons, but proposes, however, to confer on the county councils and county borough councils duties which Captain Gunston's bill left to boards of guardians. New clauses are added on town planning. They propose to make the county councils statutory town planning authorities. Other clauses deal with the salaries of medical officers of health, propose that these shall be full time officers and provide that the Minister of Health may prescribe the qualifications of medical officers and health visitors. Schemes are to be submitted to the Minister for contributions from counties and county boroughs for financial assistance towards the cost of services rendered by voluntary associations for maternity and child welfare.

The Parliamentary Medical Committee has not yet considered this bill in detail.

Debate on the Address.

During the debate on the address on November 12th Mr Hayes drew attention to the Government's policy in regard to tuberculosis ex-service men. The treatment of these men, whose disability was accepted as due to war service, had been handed over by the Ministry of Pensions to the Ministry of Health. A case of a man aged 50 in Liverpool who was in receipt of 100 per cent pension for tuberculosis had come to his notice. The man was living in a slum with five other members of his family. On the advice of his panel doctor the man applied for sanatorium treatment but he was informed by the local representative of the Ministry of Pensions that his case had been referred to the local authority which in Liverpool was the Port Sanitary Hospitals Committee. After consideration that committee decided that they could not admit the man to any of their sanatoriums. He had therefore to return home to bed. What he (Mr Hayes) was concerned about was the statement by the local authority that they could not admit this man to a sanatorium while there were other patients on the waiting list who had not yet had an opportunity of benefiting from sanatorium treatment. Further the local authority stated that sanatorium accommodation on Merseyside was fully occupied so that if this man was given a bed another patient would be deprived of it.

Dr SIMES said that the unemployment problem had not been seriously tackled. Since the war nearly £400,000,000 had been spent just to keep people alive, and no more than alive. There was nothing to show for it, and these people had been subjected to a very serious ordeal and to great suffering and privation. The problem should have been tackled just like the war and a general staff should have been appointed to deal with it. It was not sufficiently realized that the amount given in unemployment relief was not sufficient to keep in health those to whom it was given.

The Ministry of Health sometimes stated that there seemed to be evidence that people were making claims for national health insurance who were not entitled to do so. He believed a very great deal of that was primarily due to unemployment and that the physique and health of the people were being steadily undermined by it. That in itself from the point of view of the physical fitness of the nation, especially in view of the revelations of the war was a subject which should appeal to all patriotic people. While he agreed with emigration the Canadian winter was very hard and he was anxious that conditions in Canada and Australia should be such as would justify them in encouraging people to go there. A great deal of injustice had been done to the disabled ex-service men. They had found it practically impossible to obtain work and many of them, with their small pensions, had had a very miserable time. Their pensions ought to be brought up to the subsistence level.

Dr VERNON DAVIES said that if the Labour party instead of going about making so many vain promises would concentrate on the work to their hand and see that the conditions of the workers abroad were brought closer to English standards, we should very quickly overcome one of the great causes of unemployment. Dr Shiels had spoken about unemployment benefit but he was criticizing an Insurance Act and not a relief scheme. It was never suggested that the money paid under that Act would be sufficient to keep a healthy man or woman in good condition but it was an insurance scheme, and those concerned

were getting a good return for the contributions that they had made. Apart from all that the unemployment problem was causing great anxiety in the country. People generally had no conception of what people in Lancashire had been going through during the last seven years. Recently in Lancashire he was astonished to see how well dressed the people were but he was told that in more than one place they were saving money on their food. They were not spending half as much on food as in the good times. He suggested that an effort should be made to bring peace in the cotton industry.

Mr RHYNS DAVIES said that in some of the mining districts local authorities who had hitherto been able to provide meals for necessitous school children were in dire straits financially. In a little district in his division called Aspall there was a population of 7,000. Nearly all the pits were closed, and some of the men had been unemployed for two, three, and even four years. The infantile mortality rate which was 85 per thousand for Great Britain as a whole, was 128 per 1,000 in that area. The Government ought really to study the terrible effect of unemployment on infantile mortality as well as on mortality generally. The figures relating to the payment of sickness and disablement benefits to the insured population of this country were an additional proof that the people were suffering much more severely than many members and the Government would admit.

National Health Insurance.

Increase in Expenditure on Sickness and Disablement Benefits.—On November 8th Sir WALTER RE FREE asked Mr. Chamberlain whether he had any evidence that the increase in the expenditure on sickness and disablement benefit was in any way attributable to the administration of certain friendly societies or to the laxity of doctors in the issue of certificates and if so, what remedial action he was taking. Mr. CHAMBERLAIN said that, in endeavouring to ascertain how far the recent abnormal increase in expenditure on sickness and disablement benefits was attributable to causes which could and should be removed, he was receiving the full co-operation of approved societies of all types in inquiries for the purpose of securing that their administrative methods should be fully efficient and of the Insurance Acts Committee of the British Medical Association who recently submitted to a conference of Local Medical and Panel Committees a number of detailed proposals (to which the conference agreed with certain amendments) for improving the procedure under which insurance practitioners at present carried out their duties with respect to medical certification.

The Retail Pharmacists Union and the Drug Fund.—Dr. LITTLE asked Mr. Chamberlain on November 8th if when making the agreement with the Retail Pharmacists Union relating to the National Insurance Drug Fund, described in the annual report of the Ministry of Health 1927-28, the British Medical Association was consulted, if its approval of that agreement was obtained and if in the view of the unanimous condemnation of the agreement as being against public policy recorded by two full sessions 1927 and 1928 of the annual conference of Panel Committees he would rescind that agreement. Mr. CHAMBERLAIN replied that before the agreement with the Retail Pharmacists Union was actually concluded the Insurance Acts Committee of the British Medical Association were made acquainted with its terms by letter and subsequently a conference took place at the Ministry, when various criticisms and suggestions were fully discussed. The approval of the British Medical Association to the agreement as a whole was not invited, and had not therefore been obtained. At the conference of Panel Committees in 1927 considerable difference of opinion was manifested, though the resolution mentioned by Dr. Little was ultimately passed. It had been reaffirmed without discussion in 1928. He was not prepared to rescind the agreement.

Local Government Bill Position of Voluntary and Poor Law Hospitals.—On November 9th Dr. LITTLE asked Mr. Chamberlain what arrangements had been made to secure the co-operation of voluntary hospitals and the hospitals now under Poor Law administration as contemplated in the Government's bill for the reorganization of local government. Mr. CHAMBERLAIN said this problem had been actively discussed in many quarters for a considerable time. Definite local arrangements on the new basis could not be entered into until the Local Government Bill became law. Dr. LITTLE asked if any estimate had been made of the probable cost of the provision at municipal hospitals of medical and nursing services on the same scale as now obtained at the voluntary hospitals, where the medical services were mostly unpaid, and if he could furnish any information as to the measure of increase in the rates likely to follow upon the competition of the municipal hospitals with the voluntary hospitals in the event of no co-operation being achieved between these two classes of hospitals. Mr. CHAMBERLAIN answered that in the meantime it was impossible to accept the assumptions underlying this part of Dr. Little's question or to have any estimates upon them.

Grants to Ex-service Men.—During the year ended in September ninety pensions had been granted to ex-service men or their dependants whose claims were outside the seven years limit. About 1,400 patients including cases of re-amputation and second disabilities received a grant or further grant under special sanction during the past twelve months.

Unnecessary Noise.—Answering questions on November 8th Colonel ASHLEY said he had convened a conference of all interests concerned to advise what steps could be taken to mitigate unnecessary noise made by mechanically propelled vehicles. Sir

WILLIAM JOYNSON HICKS stated that since January 1st the police had brought 10,000 prosecutions for noisy motor cycles.

Marriage of Mentally Deficient Persons.—Mr. CHAMBERLAIN told Mr. Erskine on November 8th that he could not undertake at present to initiate legislation dealing with the far-reaching and controversial issue of the marriage of mentally deficient and unfit persons. Many local authorities were making further provision for mental defectives, and others were being urged to take action. He anticipated that one of the results of the scheme of local government reform would be that local authorities would have spare accommodation available for this and other services of public health.

Foot-and-mouth Disease.—On November 12th Mr. GUINNESS told Mr. Alfred Williams that twenty-three outbreaks of foot and mouth disease had been confirmed since August 1st, 1928, involving eight new centres. No fresh sources of origin had been discovered.

Examination of Carcasses for Caseous Lymphadenitis.—Sir KINGSLEY WOOD replying to Mr. W. Thorne on November 12th said it was the practice in the City of London to examine all sheep's carcasses for caseous lymphadenitis before they were distributed to retailers. The Port of London Sanitary Authority had recently decided to examine for this disease a percentage of the carcasses arriving at the docks and to release the remainder to cold stores in the London area on condition that they were not removed therefrom without the permission of the local medical officer of health. The Minister of Health hoped it would be possible to arrange for uniform action at all ports for preventing the distribution of meat infected with this disease.

Prevention of Contamination of Food.—Sir KINGSLEY WOOD in reply to Mr. Couper on November 12th said that the Public Health (Meat) Regulations and the Public Health Act 1925 contained provisions for preventing risk of contamination of food offered for sale. The Minister of Health did not think there was any need for further legislation to extend the powers of control already possessed by local authorities.

Metal-grinding Industries (Silicosis) Scheme.—On November 12th Sir W. JOYNSON HICKS told Mr. W. Thorne that no medical test for employment was imposed by the metal grinding industries (silicosis) scheme. Workmen employed by certain firms in those industries had been required by their employers for the purposes of insurance, to pass a medical examination and some of them who failed to pass had been discharged but he had no information on the number affected. A workman employed at or after the commencement of the scheme had a right to claim compensation for total disablement after he had left the employment provided he had been employed in dusty processes within the previous three years.

Slum Areas.—Mr. CHAMBERLAIN replying to Mr. Bennett on November 12th said that it was the intention of the Government to introduce at the earliest practicable moment legislation dealing with slum areas, which would provide for an amendment in certain respects of Section 46 of the Housing Act 1925.

Disinfection of Dental Tubules.—Sir G. HENNESSY replying on November 13th to Mr. Johnston, who asked whether he was aware that Dr. Watson of Cathcart Glasgow had submitted to the Medical Research Council in 1927 proposals for the better disinfection of the tubules of teeth, and that repeated requests for a report on this process had been asked for without result, said that Dr. Watson had made a claim of the nature indicated. This was insufficient however for any report to be made upon it. Dr. Watson's proper course was to follow the customary practice of making full scientific publication of his methods and results with a view to trial and criticism by his professional colleagues.

Salaries of Post Office Medical Officers.—On November 12th Viscount VOLMER informed Mr. Graham Little that the salaries paid to officers in the Post Office Medical Service were recently the subject of a claim before the Industrial Court, who had referred the matter back to the parties for reconsideration. Pending further developments, Lord Volmer could not make any statement in the matter.

Bills

The Expiring Laws Continuance Bill was introduced in the House of Commons on November 8th.

On November 12th Mr. CHAMBERLAIN presented the Local Government Bill to amend the law relating to the administration of poor relief, registration of births, deaths and marriages, town planning and local government. The bill was formally read a first time.

Sir JOHN GILMOUR on November 12th presented the Local Government (Scotland) Bill. The measure transfers to county councils and the town councils of certain burghs in Scotland the functions of existing local authorities relating to poor relief, lunacy and mental deficiency, education, public health and other matters. The bill was read a first time.

A bill for the better regulation of road vehicles has been introduced into the House of Lords by Viscount CECIL of CHILWOOD. It requires all drivers to take out a licence after examination into their skill and physical fitness and proposes to empower the Ministry of Transport to make regulations requiring the production by the applicant for a licence of evidence, by a doctor's certificate or otherwise, that he is fit to drive a mechanically propelled vehicle.

Mr. Chamberlain stated on November 8th that he had not received the report of the Committee appointed to inquire into the London Lock Hospital.

Medical News.

THE first extra Metropolitan dinner of the University of London Medical Graduates' Society will be held at the Queen's Hotel, Birmingham, on Friday, November 23rd, at 7.30 for 8 p.m. The president, Sir St. Clair Thomson, will be in the chair. The honorary treasurer, Mr. McAdam Eccles, one of the honorary secretaries, Dr. Dorothy Hare, Sir Charlton Briscoe, and Professor Hey Groves, among others, have promised to attend. No tickets are being issued, and any University of London medical graduates wishing to be present are requested to communicate with Professor W. Billington, 58, Harborne Road, Edgbaston, Birmingham. The price of the dinner is 10s. 6d., payable to the hotel.

THE annual reunion dinner of the British Serbian Units Branch of the British Legion and of all friends of Serbia will be held on Saturday, December 1st, at 7.15 p.m., at the Victoria Mansions Restaurant, Victoria Street, Westminster. The president, Dr. Alice Hutchison, will be in the chair. Tickets can be obtained from the honorary secretary, J. R. Chappell, 123, Queen's Road, W.2.

THE fourth annual Norman Lockyer Lecture will be given, under the auspices of the British Science Guild, by Professor J. Arthur Thomson, of the University of Aberdeen, on Wednesday, November 28th, at 4.30 p.m., in the Goldsmiths' Hall, Foster Lane, E.C., the subject being "The ultimate value of natural history." Applications for tickets should be addressed to the secretary of the Guild, 6, John Street, Adelphi, W.C.2.

SIR ROBERT ARMSTRONG JONES will deliver four lectures on physics at Gresham College, Basinhall Street, E.O.2, on November 20th, 21st, 22nd, and 23rd, at 6 p.m. The first will deal with care of mental illness, the second with the brain and sense organs, the third with old and new psychology, and the last with sleep. Admission is free to the public.

DR. S. VERE PEARSON, physician to the Maudsley Sanatorium, will read a paper before the North Western Tuberculosis Society on pitfalls in the diagnosis of pulmonary tuberculosis, on Thursday, November 22nd, at 3.15 p.m., in the Public Health Laboratory, York Place, Oxford Road, Manchester. The attendance of all medical practitioners is invited.

A DISCUSSION on ante natal methods with special regard to disproportion will be held at a meeting of the Maternity and Child Welfare Group of the Society of Medical Officers of Health at the Royal Free Hospital, Gray's Inn Road, W.C.1, on Friday, November 24th, at 8 p.m. The speakers will include Professor Molloy, Dr. Eardley Holland, Professor F. J. Browne, Dr. Annie McCall, Dr. Alec Bonrne, and Dr. Lane Roberts. On the following day, at 2 p.m., Professor Molloy will hold an ante natal clinic and Dr. Chodak Gregory a children's clinic at the hospital.

THE Fellowship of Medicine and Post Graduate Medical Association announces that a lecture will be given by Mr. L. C. Rivett on Monday, November 19th, at 5 p.m., at the Medical Society of London, 11, Chandos Street, Cavendish Square, on "The signs and symptoms of the common disorders of the menopause." On Tuesday, November 20th at 4.30 p.m. Dr. Saxby Willis will lecture on bronchiectasis at the Royal Chest Hospital, and on the same day, at 11 a.m., Mr. Graham Brown will give a clinical demonstration in the ear, nose, and throat department of Charing Cross Hospital. Demonstrations will also be given on Wednesday, November 21st, at 4 p.m., by Dr. E. G. French at the Wellcome Museum of Medical Science on "The etiology of various skin diseases," and on the following day, at 3.30 p.m., by Mr. Cardell at the Central London Ophthalmic Hospital. There is no fee for these lectures or demonstrations. A two weeks course in neurology at St. Peter's Hospital and a four weeks course in neurology at the West End Hospital begin on Monday, November 19th. Other courses are in progress at the London Lock Hospital, in venereal diseases, in ophthalmology at the Royal Westminster Ophthalmic Hospital, and in medicine, surgery, and gynaecology at the Royal Waterloo Hospital. Copies of all syllabuses and information relating to the general course of the Fellowship may be obtained from the Secretary, 1, Wimpole Street, W.1. The list of special courses for 1929 is now available and will be sent on application.

A SPECIAL course in infant diseases for medical officers of welfare centres and others will be given at the Infants Hospital, Vincent Square, Westminster S.W. from December 3rd to 16th. The fee for the course is £3.3s. Further information can be obtained from the Secretary of the Fellowship of Medicine, 1, Wimpole Street, W.1.

DR. T. RITCHIE ROGER, a recent chairman of the East Yorks Division of the British Medical Association, has been unanimously elected sheriff of the city of Hull.

THE following members of the medical profession were among the mayors elected on November 9th: Dr. H. J. Campbell (Dartmouth), re-elected, Dr. J. F. C. Hossack (Ipswich), Dr. I. G. Modlin (Sunderland), Dr. L. Price (Nuneaton), Dr. H. Robinson (Kensington).

AT a meeting of the Joint Tuberculosis Council on October 17th Dr. Sutherland reported on the conference at Rome. A valuable statistical study on "The fate of young children in tuberculous households" was presented by Dr. Lissant Cox. A total of 1,023 children up to 5 years had been considered, and the figures controlled by standard modern statistical methods. The Lancashire figures of deaths of young children from tuberculosis do not agree with those of Professor Calmette. A striking point revealed by this study was the number of deaths from non-pulmonary tuberculosis in young children exposed to infection from pulmonary cases, which was some ten times as great as that of the controls. The council recorded its appreciation of the care taken by the chairman and hon. secretary to make the dinner to transatlantic colleagues such a brilliant success.

LORD MELCHETT presided at the eighth annual reunion dinner of Queen Alexandra's Hospital for Officers, held at the Hotel Cecil on November 8th. A letter of good wishes to all present from H. R. H. Princess Victoria was read. The chairman paid a tribute to the work done at the hospital by all the staff, and in particular by Mr. Herbert Paterson, who acted throughout the war as honorary surgeon in charge. Lord Waring, who equipped and maintained an annexe to the hospital, was also present.

AT the last session of the League of Nations Health Committee, which concluded on October 31st, Dr. Lutrario, president of the Malaria Commission, dealt with recent criticisms of the Commission's work, to examine which a conference of leading malarialogists met at Geneva in June. A summary of the report of this conference was published in the *Journal* of October 13th (p. 664). The conference agreed that a close study of local conditions was of the first importance, especially as there did not exist any method of fighting malaria clearly preferable to all others. It proposed also the creation of a permanent and autonomous scientific central research organization. As a result of the conference, Dr. Lutrario stated, the danger of opinion on the methods of dealing with malaria had disappeared. Several subjects suitable for international study have been suggested, and the president and members of the Health Committee in consultation with Dr. Lutrario, will decide which studies can best be undertaken within the limits of available resources.

A BILL to amend the Pharmacy and Poisons Ordinance is to be considered at the next meeting of the Legislative Council of British Guiana. Under Section 3 of the bill it is provided that "No person shall keep open shop for selling, retailing, dispensing or compounding, or shall sell, retail, dispense or compound drugs or poisons or patent or proprietary medicines unless such drugs or poisons or patent or proprietary medicines are sold, retailed, dispensed or compounded in a shop which is under the immediate personal control, management, and supervision of a duly registered chemist and druggist employed therein for such purpose who is not acting in a similar capacity for any other person or in any other shop and unless such drugs or poisons as aforesaid are sold, retailed, dispensed or compounded by or under the direct charge and supervision of such chemist and druggist." It is noteworthy that under this section patent and proprietary medicines come under the same restrictions as those applying to drugs and poisons, whereas in this country there is no legislative provision restricting the selling of these articles to registered chemists and druggists. Under Section 7 (1) of the British Guiana bill the Governor in Council is empowered to authorize the sale of drugs and patent or proprietary medicines by persons not registered as chemists and druggists in areas remote from the coastlands.

A VERBATIM report of the proceedings of the National Conference on Maternity and Child Welfare, which was held at the London Guildhall in July under the presidency of Sir George Newman, has been published by the National Association for the Prevention of Infantile Mortality, and may be obtained from the office of the association, 117, Piccadilly, W.1, price 2s. 6d. An account of some of the more important discussions was given in the *Journal* on July 14th (p. 59). The full report contains a valuable collection of information and opinion on all phases of the subjects under discussion. The association has also published a new and effective poster embodying a warning against the use of the "dangerous, dirty, deadly dummies."

In the annual report of the medical department of the United Fruit Company for 1927, a generously illustrated and well printed volume of over 350 pages, an account is given of a medical service under private enterprise on a scale practically unknown in Europe. The company, whose head office is in Boston, has extensive plantations in the West Indies and throughout Central America, with its own rail ways and ships. Its medical department includes over fifty qualified practitioners, and it maintains an extensive system of hospitals and dispensaries to provide for the needs of the 228,000 persons dependant upon it for treatment. The greater part of the report consists of original articles, case notes, and memoranda contributed by members of the staff, a large amount of space being devoted to a discussion on the use of plasmoquin in the treatment of malaria. Dr W. E. Deeks believes that it promises to be the most important discovery for malaria control since the value of quinine in malaria was first recognized. An interesting section is devoted to snake-bite problems, in the investigation of which the company is co-operating with the Museum of Comparative Biology at Harvard University. A snake census in Honduras in 1924 and 1925 yielded the necessary basic information, which has since been amplified from other sources. Arrangements have been made with the Antivenom Institute of America (a subdivision of the Mulford Biological Laboratories) for the supply of specific antivenoms, a note on the preparation of these appeared in our columns on December 18th, 1926 (p. 1206). The company has provided a serpentarium at Tela, Honduras, and readers assist also in the capture of snakes and in their transportation.

ACCORDING to a recent publication of the office of statistical investigations of the United States Public Health Service a definite recrudescence in the incidence of malarial fever in the United States since 1925, the recorded rate in the first spring of 1928 being the highest since 1918. This recrudescence has not yet appeared in other countries.

THE increase in the number of medical practitioners in Switzerland in 1928 was 39 per cent over that in 1926, while the increase in the number of inhabitants was only 6 per cent, so that there was 1 doctor to every 1,238 inhabitants. In Austria, where, as in this country, there is a considerable excess of medical practitioners, there is 1 doctor to every 966 inhabitants. In Germany the proportion is 1 to 1,500, in Holland 1 to 1,550, in France 1 to 1,603, in Denmark 1 to 1,629, and in Spain 1 to 1,222.

A COMMITTEE has recently been formed in Paris, under the patronage of members of the French Academy and the deans of the French medical faculties, to honour the memory of the historian, Dr Cabanès, who died recently. The president of the committee is Professor Sbrayès of Bordeaux, president of the Association of French Medical Journalists, and the treasurer M. Albin Michel publisher, 22, Rue Huyghens, Paris XVI* to whom subscriptions should be sent.

UNDER the title of *Wells and Springs of Warwickshire* the Geological Survey has issued a further memoir, by Mr L. Richardson, of the series describing in detail the sources of underground waters in the counties of England. The author surveys the geological structure of the county in his introduction and proceeds to review serially in the sources of water supply in each rural and urban district, and each municipal and county borough. A considerable amount of space is given to Birmingham and Coventry, while Leamington Spa and its waters are fully described. Numerous water analyses are given, there are several useful sketch maps and sections, the bibliography is very extensive. The book is published by H. M. Stationery Office, London, or may be obtained through any bookseller the price being 5s net.

MESSRS SIEBE, GORMAN and Co., Ltd., safety engineers, etc., 187, Westminster Bridge Road, London, S.E.1, have issued a new catalogue of breathing apparatus and other protective and first-aid appliances for all purposes. The catalogue includes descriptions of a wide variety of apparatus for use in physiological research and other purposes ancillary to medical science. This includes apparatus for determining the basal metabolic rate, and for determining the total respiratory exchange in man, a recording spirometer, an ergometer, sphygmomanometers for blood pressure tests, and apparatus for air and gas analysis, etc. Various types of resuscitation apparatus are shown, and the catalogue gives in short almost every conceivable kind of equipment for "safety" work in industry, mining, and other fields.

AT a recent conference the Smoke Abatement League of Great Britain adopted a resolution expressing the opinion that the production of solid smokeless fuel is now upon a sound commercial footing and calling upon local authorities in general, and health departments in particular, to take steps to popularize the use of such fuels, and so to help to solve the domestic smoke problem. In this work the League

pledged itself to co-operate. A memorandum circulated to medical officers of health and public health committees advocates the organization of exhibition, health weeks, lectures, and displays, and the widespread distribution of literature. Pamphlets in popular language are being prepared for this purpose. The memorandum states that there are now several excellent fuels on the market, which are superior to raw coal in respect of cost and efficiency, and are infinitely cleaner. Attention is also drawn to the value of the now quantities of gas coke, and to the advantages of gas and electricity over raw coal. The memorandum concludes: "It is hoped that progressive health departments and municipalities, recognizing the gravity of smoke pollution, will take immediate steps to mitigate the evil, and to restore the atmosphere to that state of purity which is essential to the health of every city and town."

THE following appointments have recently been made in the foreign medical faculties: Dr C. Cenci of Cagliari, professor of nervous and mental diseases at Bologna; Dr G. Boscchi Arana professor of operative surgery at Buenos Aires; Dr A. Gutlich professor of otolaryngology at Cologne; Dr V. Gerbasi of Bari, professor of nervous and mental diseases at Genoa; and Dr S. Weber, professor of radiology at Riga.

THE late Dr Edgar March Crookshank emeritus professor of bacteriology at King's College Hospital, and treasurer of the Royal Veterinary College, left estate of the value of £73,123, with net personalty £49,472.

THE first stone of a leper sanatorium was recently laid at the Hôpital St. Louis, Paris, under the patronage of the Order of Malta.

THE well known medical publisher, M. Pierre Masson of Paris, has recently died.

Letters, Notes, and Answers.
